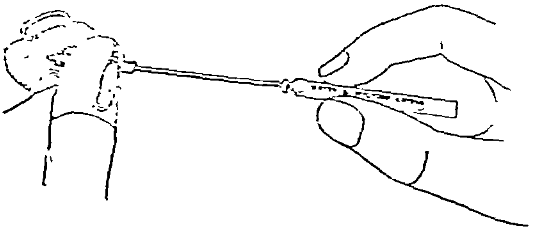
Studies in Anatomy from the Anatomical Department of the University of Manchester. Vol. III. Edited by ALFRED H. YOUNG, M.B. Edin., F.R.C.S. Eng., Professor of Anatomy. Manchester: At the University Press. 1906. Pp. 289. Price 10s. net.—This forms the third volume of the Studies in Anatomy issued by the Council of the Owens College and contains contributions of considerable interest. There are ten papers included, but six of these are reprints from the *Journal of Anatomy and Physiology.* The new contributions are four in number. A paper by Professor A. H. Young and Dr. W. Milligan shows the anatomical and developmental continuity of the Eustachian tube, tympanum, and mastoid antrum. Attention is drawn to the very early development of mastoid air cells and some observations are appended on the treatment of septic inflammation of the tympanic cavity. Dr. J. Dunlop Lickley discusses the Morphology and Development of the Human Sternum. This paper is a summary of a larger monograph which was presented as a thesis for the M.D. degree of the University of Glasgow. The paper is critical and instructive and questions some of the recent deductions of Professor A. M. Paterson and others. A copious bibliography is appended. Dr. J. Cameron contributes a paper on the Development of the Optic Nerve in Amphibians, in which he shows that the nerve fibres are formed by a combination of the central and peripheral modes of origin. The paper is welcome considering the discussions which have lately arisen in connexion with the development of peripheral nerves. An investigation by Dr. C. W. S. Saberton on the constitution of the nerve plexuses of Troglodytes Niger embodies the results of a very laborious research. The reprints in the volume are papers by Professor Arthur Robinson on the Formation of the Pericardium; Professor Peter Thompson on the Fasciæ of the Pelvis; Professor Young and Professor Thompson on Abnormalities of the Renal Arteries; Dr. F. C. Moore on the Unsymmetrical Kidney; Dr. Lickley on the Morphology of the Human Intertransverse Muscles; and Professor Young on the Lumbar Arteries. Most of these contributions are already well known to English anatomists. The volume is well printed and bound. It speaks well for the activity of investigation at Manchester.

Minor and Operative Surgery, including Bandaging. By HENRY R. WHARTON, M.D., Professor of Clinical Surgery in the Woman's Medical College of Pennsylvania. Sixth edition, enlarged and thoroughly revised. With 532 illustrations. London: Rebman, Limited. 1905. Pp. 650. Price 14s net.—The author of this work hopes that the broadened scope of its new edition will render the volume more serviceable to the student and to the practitioner. The favour bestowed on former editions has, the author says, acted on him as an incentive for keeping the book thoroughly revised and up to date. The whole volume is most liberally treated from the pictorial standpoint and the subject matter is thoroughly well arranged and explained. In successive editions the author has been led to add operations which are somewhat beyond the vague line separating major from minor surgery. Thus the book has been broadened beyond its original title in response to the expressed wishes of its readers. The great attention now paid in medical schools to operations on the cadaver and the importance of this method of instruction have led the author to include those procedures which can be advantageously practised upon the dead body, such as ligation of the vessels, amputations, excisions, operations upon nerves and tendons, and intestinal anastomosis. A number of operations which are frequently required in practice are also included, such as tracheotomy, intubation of the larynx, and the operations for appendicitis and for strangulated hernia. While this edition is therefore a comprehensive manual, covering all but what may be termed Capital Surgery, yet all the features which have met with favour in former editions are retained, including a concise description of the various bandages, surgical dressings, and minor surgical procedures employed at the present day. The art of bandaging is fully illustrated with reproductions of photographs, and a special chapter is devoted to surgical bacteriology. The subject of fractures and dislocations is photographically illustrated. The chapter on the preparation of materials used in aseptic operations and on the details of an aseptic operation is an excellent one and contains much valuable information. The directions in the section on intubation of the larynx are very clear; the author emphasises the necessity of hugging the posterior surface of the tongue closely. This edition will no doubt be as popular as the former issues have been. It is a good book.

New Inventions.

THIMBLES FOR MAKING WOOL MOPS.

THE drawback of making surgical mops by holding the cotton wool between the finger and thumb is that in order to make them clean repeated washing of the fingers is necessary and even when this is done absolute cleanliness is doubtful. To avoid these inconveniences I have had the metal thimbles shown in the accompanying figure made for the left forefinger and thumb. They are flattened and provided with several shallow and one deeper groove on the opposing surfaces, where also the metal is dulled instead of being polished. With a little practice mops of any size can be rapidly made. The thimbles, which fit on to a little metal stand, can be boiled, stand and all, before use and if they are only kept on whilst actually making the mops they can be employed for a series of cases without any further cleaning. The handles are merely for lifting them off the stand. They have been made for ear, nose, and throat work but can, of course, be used to make mops for other purposes. I have found them more convenient than Kayser's forceps, which were devised with the same object. The thimbles are made by Messrs. Mayer and Meltzer, 71, Great Portland-street, W., in various sizes.



Brook-street, W. E. CRESSWELL BABER, M.B. Lond.

A COMBINED VAGINAL DOUCHE AND STERILISER.

THE difficulty so often experienced by midwives in obtaining hot water in cases of emergency is obviated by this appliance. As it is provided with a lamp and is supported on a firm stand the midwife will always have the means of warming water so that a hot douche can be obtained in a few minutes. Again, in case the surgeon's aid is called in she can provide him with a steriliser for his instruments as it is large enough to hold forceps, &c., for sterilising purposes. Without the stand and lamp it forms an ordinary douche can. It is made of a convenient size and will easily go in the midwife's bag. *It has been made for me by* the Medical Supply Association, 228–230, Gray's Inn-road, London, W.C.

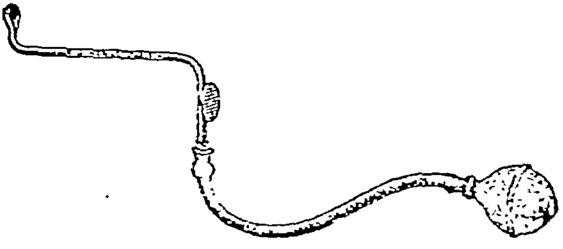
Physician-Accoucheur, Royal Maternity Charity.
Westbourne Park-road, W.

A NEW POST-NASAL SYRINGE.

THE advantages of post-nasal syringing over the more usual methods of flushing out the nasal passages are obvious. The only objection thereto consists in the somewhat greater difficulty of the proceeding. In order to facilitate this I have devised a modified post-nasal syringe which I find can be used by most people themselves with at least as much ease as the ordinary enema syringe, though, of course, there are some exceptions. The general appearance of it is shown in the illustration. The straight part of the metal nozzle is about five inches long and the extremity is turned up for a length of about three-quarters of an inch. The orifice is in the form of a deep, narrow slit, which delivers a flat jet of fluid when the indiarubber ball is compressed. The instrument is made by Messrs. C. J. Hewlett and Son, Charlotte-street, London, E.C.



Argyll-road, W. F. H. BURTON-BROWN, M.D. Oxon.

THE LANCET.

LONDON: SATURDAY, AUGUST 18, 1906.

Infantile Mortality.

WE publish this week three important articles bearing directly or indirectly upon the great question of the control of *infantile mortality*, articles which were read at the National Conference on that subject held on June 13th and 14th under the chairmanship of the President of the Local Government Board. Mr. JOHN BURNS showed himself to be fully conscious of the magnitude of the questions to be discussed, but the pressure of public affairs and of intelligence of other kinds served greatly to divert public attention from the proceedings of the Conference. It is not, however, too late to return to a subject of the first national importance, and the three contributions which we now place before our readers will afford excellent material for reflection not only to medical men but to all thinking people. Of the three articles that by Dr. GEORGE REID, medical officer of health of Staffordshire, throws the largest amount of light upon the actual causation of mortality, while the articles on milk-supply by Dr. A. K. CHALMERS and Dr. G. F. MCCLEARY indicate the directions in which remedies for the absence of breast-feeding may most hopefully be sought Dr. REID informs us that his attention was early directed towards the high infantile mortality of north as compared with south Staffordshire, the inhabitants of the former division being chiefly potters, whose women are largely engaged in factories, and those of the latter chiefly miners and iron-workers, whose women remain at home. A comparison between the two, carefully carried out over a series of years, entirely justifies the conclusion that maternal factory work is the chief and most widely operative cause of a high infantile death-rate. The figures given are conclusive. The percentage of female married and widowed factory workers to the whole female population between the ages of 15 and 50 years was taken from different localities. In five towns, in which this percentage was 12 or more, the infantile mortality was 193. In 13 towns in which the percentage was under 12 and over 6 the infantile mortality was 156; and in eight towns in which the percentage was under 6 the infantile mortality was 149. The lowest rate leaves much to be desired, but the difference between the highest and the lowest is far too great to be accidental. It appears, moreover, that the preponderant mortality of the children of female factory workers is at least partly due to defective viability induced by work during pregnancy, and on this part of the question the operation of the Midwives Act has already furnished important statistics. Up to the present time the midwives in the northern district have returned 9·4 per cent. of still-births and 15 per cent. of abnormalities in labour, against 3·2 per cent. of still-births and 6 per cent. of abnormalities in the southern. Dr. GEORGE NEWMAN, in his recent work on Infantile Mortality which we reviewed in our columns recently,[1] quotes Dr. REID'S figures, and declares that they are perhaps less emphatic than would be those of similar tables for Lancashire, where there are "seven times more married women employed than in Staffordshire."

If we leave out of consideration the manifestly considerable proportion of infants who come into the world handicapped by the operation of unfavourable maternal conditions during pregnancy, infants, that is, whose mothers suffer from long standing, exhausting labour, or unsuitable or insufficient food, we shall obviously find a chief cause of mortality, even among infants born healthy, in *the deprivation of breast-milk*, which is incidental to the absence of the mother at the factory, as well as in the ordinary character of the substitutes which are employed. Dr. CHALMERS and Dr. MCCLEARY show us how much might be done, if local sanitary authorities were acquainted with the nature of their duties and were desirous of fulfilling them, to improve the management of dairy farms and the quality of urban milk supplies; but, even if nothing were left to be desired in these respects, there would still be an active production of infantile mortality by the sheer ignorance of mothers. Sir WILLIAM BROADBENT recently characterised the indiarubber teat as "an invention of the devil," and it is by no means the only popular appliance which might be so described. The mothers among the industrial classes, as a rule, know nothing about the primary conditions of health for infants, and are guided by traditions handed down from bygone ages. A medical writer has placed on record that his instructions about the management of a sick child were departed from on the advice of a neighbour whose claims to be accepted as an authority were based upon the fact that she had "lost nine children of her own," and the experience of this writer is one that might have been anticipated. Similar things happen daily. Parents of the working classes constantly say of their baby, "We give it what we have ourselves," this including not only forms of food wholly unsuited to the infantile digestive organs, but not seldom "a sup of beer." To medical practitioners, conversant with the habits and dwellings of large classes of the poor, it is less wonderful that children die than that they survive, more especially when, as often happens, the discomfort produced by improper feeding is relieved by the administration of a narcotic. Professor RAY LANKESTER, in his recent address as President of the British Association for the Advancement of Science, dwelt with much force upon the truth that the political administrators of this country, as well as the permanent officials, are altogether unaware of the importance of the knowledge which we call science, and of the urgent need for making use of it in a variety of public affairs. He traces the defect, quite correctly, to the "defective education, both at school and university, of our governing class," but he fails to call attention to the fact that the education of the middle-class, which supplies the bulk of our "local authorities," is at least equally defective, and that the business committed to them is as badly done as that of the nation. We have had a third of a century of compulsory so-called "education" of the working classes, and the most obvious outcome of it has been to render them the prey of designing advertisers. The girls of the present day know no more than their great-grandmothers about the cooking of wholesome meals or about the nurture and feeding of infants, and that this should be so is a grave reflection upon the community.

---

[1] THE LANCET, July 28th, 1906, p. 230.

The framers of the Education Act of 1870 may, perhaps, be asumed to have had no distinct consciousness of the full meaning of the principle which was established by their legislation. That principle is, we take it, that the State asserts a degree of proprietorship in the children born within its boundaries, and hence becomes charged with responsibilities to them which it is very difficult either to limit or to define. It compels the children to undergo, at the cost of the public, a process which is described as education. It becomes responsible to the children for securing, firstly, that this process shall not be actively injurious to them, and secondly, that it shall be as useful as circumstances will permit. It becomes responsible to the public for the proper use of the public money, and is bound to see that this is not wholly wasted or thrown away. The precautions necessary for the attainment of these ends are chiefly such as were formerly supposed to devolve primarily upon parents; and hence, in whatever degree they are accepted by the State, it becomes necessary for the State to control or to supersede parental management. It is clearly injurious to an underfed child to be compelled to exert his brain about tasks; and hence, if the tasks are to be enforced, the State must see that the parent *feeds* the child properly, or must itself supply the deficiencies in this respect. Sufficiency of food bears a definite ratio to sufficiency of clothing, and this also may come within the province of the State. An infant below school age is nevertheless, if not an actual, at least a prospective, source of public expenditure, and hence the State becomes concerned to see that his earliest years are so passed that he may not be a useless investment for public money when school age is reached. It follows from compulsory education that the past liberty of parents to deal as they pleased with their children must in many respects be limited or curtailed in the public interest, and the sooner this is generally realised the sooner shall we get down to some bed-rock of principle with regard to the care and treatment of those who are to form the backbone of coming generations. Is it not time that our law makers took some thought for the descendants of our race? "Labour" Members are becoming conspicuous in Parliament, and are likely to strive after legislation by which they will hope to benefit their class. At present there is no indication that their efforts will be guided by adequate knowledge, and there is great need for the aid of science to be invoked. Infantile mortality on the one hand and a dirty and adulterated milk-supply on the other are mere symptoms of derangement in the body politic, but they are symptoms likely to be far-reaching in their consequences. The Education Board and the Local Government Board must have scientific guidance. Effectual reforms can only be attained under such guidance, and knowledge of the means by which physical health and efficiency can be secured falls strictly within the sphere of the medical profession. This knowledge is ready to come to the aid of legislation, and surely the time has arrived when legislators should be ready to appreciate the assistance offered.

Human Diet and Human Efficiency.

No catchword has been more mouthed of recent years than efficiency. Books in praise of efficiency or giving instruction in efficiency abound—we reviewed one such volume last week and gave it due praise; the efficiency of public bodies of all kinds, of the army and the navy, the War Office and the Admiralty, the House of Lords and the House of Commons, has been questioned and discussed till the very word efficiency has become almost a burden to the ear. Now, if individuals are not efficient no corporate body is likely to be so in the nation which these individuals compose, while grave difficulties face statesman and sanitarian alike when an attempt is made to decide what are the best methods for obtaining efficiency. Broadly looked at, all national schemes of education, whether for general purposes or for such special aims as those of the public services, are steps along the road to efficiency, but they are not the commencement of that road, and the beginnings of the real road are too often neglected. Efficiency looked at from the frankly medical point of view resolves itself into the health of the individual. The healthy mind in the healthy body (a phrase as over-used as is the word efficiency) none the less contains the truth, and those who are most urgent that our public work should be thorough must, if they are logical, show themselves most anxious about our public and our individual health. Some of the most important subjects upon which the proper healthy development of man and woman depends are barely touched upon in the educational schemes of to-day, whether we look upon the education of the masses or whether we regard the more fortunate thousands who grow up either in the great public schools for boys or in the corresponding institutions for girls. The strides that science has made in the last half century have not been paralleled by the art of education. The latter has been content to loll behind, noticing perhaps with admiring gaze the progress of her sister but hardly dreaming of any emulation of her activity. Is there, then, no science of living, no art of the conduct of life, that teachers may instil into the minds of their pupils? Most assuredly there is, and it is the most important of all arts and sciences. Yet to find its pursuit as a national ideal the imagination must almost return to the days of ancient Greece. We do not belong to the ranks of those who croak and cry "national decay." We believe that, despite the undoubtedly evil influence of large towns, national decadence is not upon us. The robust inheritance of British ancestry is far from worn out, but we are ardent supporters of those who wish to see no step untrodden that can lead to the finest results from the activities of our national character. Somehow, as has been said, we as a nation "muddle through and come out successfully." Who would not like to see the muddling exchanged for the strong and direct action of a nation that had studied and that was practising the science of life?

This science of life, as we comprehend it and as we would have it taught to children, has two main directions. The first leads to spiritual development and the second to the perfection of bodily health and purity. The latter is well expressed in the sacred writings of the East where bodily happiness is described as "lightness, healthiness, peace, a good complexion, beauty and grace, perfect fragrance, a melodious voice, and light excretions." To what degree is any bodily ideal of this sort put before English children? It is true that swimming-baths and open-air games are well patronised, instincts of cleanliness and a wholesome liking for bodily exercise being thus encouraged, but children should also be taught the beauty of personal hygiene, and the part which it plays in the greatness of a nation. They should be led thus from its personal to its corporate and its national application. We are not so sanguine as to believe that the evils of overcrowding and of town living generally would disappear before the clear ideas and the clean desires of a manhood and womanhood thus instructed, but undoubtedly national physique would be in less danger of degenerating at the hands of men and women who had grown up with a knowledge and understanding of proper bodily development. Our readers know so well how largely growth and development depend upon nutrition that they may, some of them, fail to realise how densely ignorant of such matters the mass of the population is. The matter is one upon which instruction might most profitably be given as part of a scheme of national education. What does the child or the young man or woman of to-day know about the nutritional values of the different kinds of food? Not one out of any ten average men or women has any simple rational principles or knowledge to serve as guide in the choice of food. This is shown by the violent faddishness and extravagant credulity of those who do make attempts to regulate their diets every whit as much as by the horrible errors of dietary so familiar to the general practitioner, and now and again made public during the proceedings at a coroner's inquest. The lower animals are more fortunate in respect of their diet than is the majority of human beings, for in the wild state the young animals are carefully guided and instructed as to their prey. They are shown what to eat and how to get it. Science and experiment have recently shed much light on the food problems that affect human beings. They have brought to light new facts as to how much food the healthy organism requires and as to what should be the nature of that food. Knowledge of this kind is of the greatest value in its relation to the economy and the health of a nation's population. Yet the dissemination of such knowledge in simple terms amongst those of an age when the habits of life are most easily and most surely formed is at present almost entirely absent.

We have been moved to some of these reflections by the perusal of a book entitled "Humaniculture,"[1] written by Mr. Hubert Higgins, an English medical man practising in Italy, whose paper in our columns last year, entitled "Is Man Poltophagic or Psomophagic?" attracted considerable attention. Those of our readers who are familiar with the work of Professor Chittenden and Dr. Robert Hutchison will have no difficulty in realising the new knowledge now at our disposal in the matter of diet, nor need we on their account lay stress upon the far-reaching effects of correct behaviour in this respect. To others desiring a simpler gospel, one that can be handed on almost without translation or exegesis to their patients, we commend "Humaniculture." Mr. Higgins is a worker upon the lines of Mr. Horace Fletcher, whose ideas and experiments in the matter of food and feeding we have previously commented on, and whose work has received the official recognition of the International Congress of Physiology. We are not prepared to support all the theories advanced either by Mr. Fletcher or by Mr. Higgins, but we recommend without hesitation much of the practice which they advocate. The old and salutary advice to eat little and to take a long time over it is the gist of their message. What is new, however, in Mr. Higgins's book is the careful clinical experiments upon which the assertions rest, and the alteration of the proteid standard which their acceptance involves. As is well known, Mr. Fletcher has succeeded in arousing enlightened enthusiasm not only in his own country of America but also in the University of Cambridge, where Sir Michael Foster superintended the work undertaken to test his views. It may seem to many that the simple practice of eating sparely and eating slowly has little to do with national questions or even with individual and moral advantage. Even when dignified by the name of "poltophagy" chewing does not seem a matter of wide significance. Yet who is to draw the line where physical and psychical influences cease to take effect upon each other? Goutiness and a quick temper, dyspepsia and melancholy, are merely gross instances of the interaction of mind and matter, and there is no doubt that there are many associations between the two that can at present be only guessed at. Without attributing too much to the influence of food, we may safely assume that the nation which boasts the most rationally fed individuals will, in the long run, have the best chance in international struggles. We cordially welcome any attempts to educate our population, either through or independently of the medical profession, in the principles of healthful diet.

◆

Employment for Working-class Consumptives.

THE after-care and the possibilities of occupation for the consumptive patient of the operative classes together constitute a sociological and economic problem of considerable importance and of very great difficulty. A carefully thought-out and highly suggestive contribution to the discussion of this problem by Dr. M. S. Paterson and Dr. F. C. Shrubsall was published in THE LANCET of July 28th, p. 217, and is worth very careful consideration by all who may have to give advice to such patients. It must be admitted at the outset, as the authors claim, that the advice is often given to such patients to change their occupation and to obtain "open-air" employment without due consideration of the difficulties liable to be encountered in effecting such a change. In other words, the advice, though eminently sound in theory, is impracticable.

---

[1] Published by Frederick A. Stokes Company, New York. Pp. 355, 8vo, price $2.

Dr. PATERSON and Dr. SHRUBSALL point out very forcibly how absolutely hopeless may be the outlook of an unskilled labourer, or even a man with an indoor trade or occupation, when he endeavours to obtain outdoor employment of which he has no skilled knowledge; and as they very pithily remark, "there is a certain tendency to forget that starvation is a more serious trouble than tuberculosis." The conclusion arrived at, after a very careful discussion of the possibilities usually suggested to the patient with arrested tuberculosis, is that so far as possible he should return to his own trade, while those without a trade should be largely governed in their choice of an occupation by their wage-earning capacity thereat. The authors further refer to the statistics of German sanatoriums, which seem to prove that cases discharged as quiescent or arrested are capable of returning to their former occupations for periods of three, four, or more years.

With regard to some occupations, the ordinary conditions of work being not unfavourable, the advice to return to their former duties is obviously sound; this applies with especial force, as Dr. PATERSON and Dr. SHRUBSALL urge, to vanmen, tram and omnibus drivers, and most classes of railway servants. It is, however, in the case of those whose work has to be carried out under less favourable conditions that the problem is so difficult, as, for example, those working in factories, workshops, offices, and warehouses. The alternatives usually suggested to patients in such circumstances, after arrest or improvement of the disease, are carefully and fully criticised by the authors. Considering first the suggestion that the patient should obtain some open-air occupation, preferably in the country, they point out that they are then likely to swell the already crowded ranks of unskilled labour for which they are not well fitted, and thus to earn less than they did at their former occupation; hence they are liable to sink into conditions unfavourable to their future progress. The second alternative often put before them is that of emigration; here, again, it should be remembered that unless the person emigrating has some skilled occupation or some special employment guaranteed he is likely to drift into unsuitable places or to fall upon hard times. The third alternative, that of going to sea in some capacity, whether as steward or purser's assistant, is one which is hardly likely to be recommended by anyone knowing the conditions under which they may have to live, so graphically outlined by Dr. PATERSON and Dr. SHRUBSALL in their paper. Dr. PATERSON'S and Dr. SHRUBSALL'S contentions are reinforced in two letters which we publish in THE LANCET of August 11th. One of the writers, Dr. W. G. KINTON, the resident medical officer, Mount Vernon Hospital for Consumption and Diseases of the Chest, rightly remarks that energy might well be expended in concentrating attention on the conditions under which patients have to return to work, instead of regarding only the nature of the work itself. He also lays stress on the importance in enlightening the general public on the general laws of hygiene, so that patients may find help on all sides in continuing the correct mode of life necessary to them. This is a point upon which we have frequently insisted. Mr. T. H. A. VALINTINE writes with especial reference to the matter of emigration, and points to the necessity of great caution being observed by medical men or by friends before discharged patients are recommended to emigrate. Unless they are sure of immediately finding suitable employment on arriving in a new country they may simply starve, or be compelled to face hardships that will interfere with their convalescence.

If we turn to consider the outlook of such patients as return to their former occupations after treatment at a sanatorium or a special hospital, we find that the education as to the advantages of fresh air, ventilation, suitable diet, and self management, which they have received, should enable them to work under better conditions, and even to instruct those among whom they work. Again, their productive or wage-earning capacity is likely to be greater than at a new occupation assumed without special knowledge and against competition, and this is a point very strongly insisted upon by the authors in their paper and one which has influenced them strongly in arriving at their conclusions. We can in most respects cordially endorse the recommendations given by Dr. PATERSON and Dr. SHRUBSALL. It is a familiar fact in out-patient practice at both general hospitals and special institutions for diseases of the chest that patients with chronic tuberculous disease of the lungs go about their work for years, and support themselves and often their families without undue strain, and, so far as can be seen, without markedly prejudicial effect upon the course of their disease. At the same time it must be admitted that in many cases it is practically impossible for the patients to resume their former work—e.g., men invalided from the navy or army, and those whose occupation entails work in hot or moist air, such as laundry work, must find a new outlet for their energies; while in the case of domestic servants, especially those having care of children, fear of infection will preclude their resumption of their duties. It is in such cases that it is extremely difficult to give useful and practical advice, and we cordially echo Dr. PATERSON'S and Dr. SHRUBSALL'S hope that their admirable paper may "at least draw attention to the subject and so help the unfortunate consumptive to be advised thoughtfully as to his future."

Annotations.

"Ne quid nimis."

THE VENTILATION OF THE HOUSE OF COMMONS.

IN a report recently published the last word has been said, even in the light of bacteriological science, as to the defects of the air-supply of the House of Commons. The recommendations contained in this report have already been foreshadowed in an annotation in THE LANCET of April 1st, 1905, in which a report on the quality of the air in the House by Dr. M. H. Gordon was discussed. A Select Committee, which was appointed under the presidency of Sir Michael Foster, has come to the conclusion that on the whole there was little to be said against the quality of the air-supply, but at the same time it acknowledged that this conclusion was opposed to the common experience of many Members of the House, whose opinion it was that the air lacked freshness, that there was missing in it the important element of vitality. It is probable that the whole question is after all one of suitable temperature and humidity, and we understand that further observations are to be made on these important points. We very much doubt if either the chemistry or the bacteriology of the air of the House of Commons has anything to do with the depressing effects complained of, or with the prevalence of influenza amongst the Members at a time when that disease was epidemic. We still hold to the belief that the physics of the air-supply of the House is wrong, and we are confident that when the temperature and humidity of the air are controlled in accordance with healthy requirement little more will be heard of the unhealthiness of the atmosphere in the legislative chamber. Meanwhile it is interesting to note that the evils arising from dust promise to be mitigated by the use of a vacuum cleaner, and already some half hundredweight or so of dust has been removed weekly from the floor and precincts of the House.

THE GERMAN LANGUAGE AND MEDICAL MEN.

The British Association for the Advancement of Science at its recent meeting considered the question that was brought forward by Mr. J. G. Robertson of the position of German in the educational curriculum. The proportion of medical men in this country who are able to read German books is very small, yet the number of German books worth reading is very large. The amount of knowledge of the language necessary for profitable perusal of technical books is so comparatively slight that it is a great pity that the necessary trouble is not more often incurred to acquire this knowledge. To any man who has mastered German enough to enjoy its general literature there is open an enormous field of philosophy, poetry, and romance, different from, yet almost the equal of, our own inheritance in this respect. Even without attaining to this point, however, medical men can derive great profit by the smaller knowledge sufficient for technical works. In many branches of science at the present day the German contributions are perhaps the most important of any, and in all branches of medicine they are, at any rate, very far from being deserving of neglect. Mr. Robertson dilated upon the unhappy decline of German as a school subject in England in recent years. Presumably it is secondary to this ill-merited neglect in schools and in universities that there is in our own profession so comparatively small an appreciation given to the wealth of good material provided by German scientific writers for anyone who is to a sufficient extent master of the tongue. German is undoubtedly a difficult language. Enough German, however, to read with profit technical books is not beyond easy acquisition, given moderate perseverance.

THE ANALYSIS OF THE WATER FROM THE HOLY WELL OF ZEM ZEM.

According to an analysis which we have made of a sample of water taken recently from the holy well of Zem Zem the sanitary condition of this precious fluid has made little advance during the past quarter of a century. The present makes the fourth opportunity we have had of making such an analysis, the results of previous examinations having been recorded in The Lancet of Jan. 5th, 1884, p. 33; May 14th, 1892, p. 1075; and Jan. 31st, 1903, p. 327, respectively. The recent specimen examined was forwarded to us by Dr. Frank G. Clemow of Constantinople, British Delegate to the Ottoman Board of Health. The sample was contained in a hermetically sealed tin flask. When undisturbed the water was quite bright, but it contained a sediment of a rusty colour and examination proved this deposit to consist largely of hydrated oxide of iron. There was a distinct pressure in the flask and on opening it a perceptible quantity of gas escaped, which was probably nitrogen. There can be little doubt that the metal container had acted upon the nitrates and reduced them to nitrites and eventually ammonia, in the same way as would the metals copper and zinc when in contact with each other, constituting a galvanic couple. As will be seen from the analyses below, the water contains a comparatively immense quantity of free ammonia. It matters little, however, in what form the nitrogen exists, whether, that is to say, in the form of ammonia, nitrites or nitrates, its only source, as a rule, must have been at some time or other organic matter. That there are manifold opportunities for organic matter to gain access to the well is made very clear from the accounts of many travellers who have witnessed the sacrifices of beasts which are annually held in the neighbourhood of the well. It is probable that the infiltrations of countless carcasses reach the well sooner or later. Moreover, it is part of the ritual that in addition to drinking the water the pilgrim has the fluid poured over him; this water trickles away from his person back to the well, and he is doubly grateful when he discovers on retiring that the cloth round his loins is wet. What wonder then that the water presents on chemical analysis abundant evidences of impurities, and is found to contain phosphates and nitrogenous matters both in the oxidised and unoxidised state. There are, no doubt, active self-purifying processes at work, but that their intensity is not sufficient to cope with the large amount of pollution taking place is plainly apparent from analysis. It is interesting, however, to observe from the following analyses, made at intervals of several years, the variations which take place in regard to the individual items on which the sanitary or insanitary character of a water is broadly based:—

—	1883.	1892.	1902.	1906.
Total solids	464 4	235 2	350·0	200·2
Chlorine	75 5	40 7	72 1	49 7
Nitrogen in nitrates and nitrites ...	13 8	4 4	14·0	0·28
Free ammonia	0 35	0 14	0 14	0 32
Albuminoid ammonia	*Nil.*	*Nil.*	0·02	Trace.

The results are expressed in grains per gallon. The chief variation is in regard to the nitrogen in the form of nitrite and nitrate, the amount of this depending upon the original pollution and the extent to which the nitrogenous matters are oxidised by natural agencies. In the last sample examined nitrites predominated, and the water rapidly decolourised an acidified solution of potassium permanganate. The residue on evaporation gave off a sickening odour on heating and the mass blackened considerably. A very distinct reaction for phosphates was obtained. To say that the water is tainted would be a mere euphemism; it is grossly polluted. Some idea of the extent of this pollution may be gained from the fact that the water of the holy well of Zem Zem contains about 90 times more free ammonia than does the ordinary London drinking water-supply.

THE THERAPEUTIC APPLICATION OF SUGGESTION.

Dr. Mathieu, in a paper read before the Société Thérapeutique de Paris and published in the *Journal de Pharmacie et de Chimie* of July 16th, has recorded the results of his experience in employing suggestion as an aid to therapeutic treatment in the Andral Hospital. In cases of nervous dyspepsia he has obtained great success not by having recourse to pure mental suggestion but by the time-honoured method of administering various harmless substances as vehicles of suggestion (*véhicules de la suggestion*). In nervous cases where a sedative was required he has prescribed dandelion under the name of extract of taraxacum dens leonis, assuring patients suffering from *sialorrhœa* that it was an extremely powerful drug. Equally good results were obtained by prescribing applications of collodion, coloured with methylene blue, for pains in the dyspepsia of neurotic patients. Dr. Mathieu has found that insomnia can be successfully treated with chloroform water in teaspoonful doses or by one-gramme doses of sodium phosphate. The latter has given such good results as a soporific that Dr. Mathieu raises the question whether it may not exert a sedative action apart from suggestive influence. He has given injections of a simple physiological salt solution, labeled "Morphine B," and has observed—as we may say dozens of resident medical officers in hospitals must have observed before—that patients have the same craving for the substitute as they have for an actual solution of morphine. A similar solution, disguised under the name "antiphymose," when injected subcutaneously, has caused marked improvement in cases of tuberculosis; patients so treated eat and sleep better and gain in weight. Dr. Mathieu does not claim novelty for this method of treatment but he lays stress on the fact that recourse to medication by suggestion may often enable the physician to recognise the purely nervous or psychic nature of some morbid manifestations. He further suggests that the use of simple salt injections affords a criterion for the valuation of new serums, which should not be regarded as efficacious unless they produce better results than are obtained by the combined psychic and physiological action of salt solution.

SEA-NETTLES.

A MAN, practically *in puris naturalibus*, would not voluntarily throw himself upon a bank of stinging nettles, although he would be confident that no real harm would ensue. The proceeding would be attended with inconvenience and some discomfort of course, but, generally speaking, there is nothing disastrous about the sting of the common urtica, and no fear is usually entertained of its results. All that is needed after being stung with nettles is a little patience, for, as a rule, the urticaria soon passes away, as every bare-legged child knows. The same is true in the case of the sea nettle or the jelly-fish but most persons exhibit a much greater dread of an encounter with a sea-nettle than with the common stinging nettle of our hedgerows. There are instances, of course, in which constitutional symptoms arise after the stings of the jelly-fish, but these, on the whole, are rare. The jelly-fish stings much in the same way as the nettle—that is, by means of an acrid fluid discharged through a filament. The filament may be barbed or serrated and is usually coiled within cells which turn inside out on contact or pressure and thus bring the filament into touch with the body, conveying the fluid through the surface penetrated. The ordinary stinging nettle is furnished with a stinging hair from which an acrid fluid escapes when the brittle tip is broken off by contact. When examined under the microscope the hair presents the appearance of a glass tube full of fluid. On breaking the top off, as by simple contact with the hand, it will be found that some of the fluid contents have been discharged. The sting of the jelly-fish, as a rule, produces merely superficial effects, and it is usually only the larger kinds which are venomous, the small ones being without effect at all. The most formidable creature of the class perhaps is the Cyanea capillata which is distinguished by a long train of ribbon-like streamers floating after it. Contact with these streamers may result in tortures of burning and prickling, which, however, are little worse than the effect produced by the ordinary stinging nettle. The Portuguese man-of-war (*Physalia pelagica*) appears to cause more alarming results, though, as a rule, they pass harmlessly away. There is a severe and stinging pain extending up the limb, sometimes with feverishness, and there are the usual wheals on the skin, and irritation. In the same way sea anemones will sting that part of the body brought into contact with their tentacles, but again the effects, though very irritating and possibly alarming at the time, are usually transient. On the whole, the stinging effects of jelly-fish have been exaggerated, and bathers in the sea need have no greater fear of them than of the ordinary stinging nettle. The urticaria caused by both is generally relieved by the application of a bland soothing oil.

IDENTIFICATION BY FINGER-PRINTS.

IN the last report of the Commissioner of City Police some interesting figures are given with reference to the results which have been recently obtained by the finger-print method in the identification of habitual criminals. Captain Nott Bower states that during the past year 1028 persons were arrested for offences under the Prevention of Crimes Act, such as being found in inclosed premises or in other circumstances suggestive of felonious intent. Of these individuals 562 were not recognised as recidivists at the time of their apprehension, but on their finger-prints being taken and compared with the Scotland Yard registers it was ascertained that 265 of them were old offenders. This result is a striking illustration of the practical value of the simple and rapid method which has been elaborated in this country by Mr E. R. Henry; and its significance is, of course, still greater when it is considered in connexion with the more radical methods of dealing with habitual criminals towards which public opinion is gradually moving. A perfectly safe test of identity is, in fact, the first condition precedent to the adoption of any scheme for eliminating the professional criminal, or at all events for restricting his mischievous activity, and for excluding the dangers of any such miscarriage of justice as occurred in the Beck case.

ARTERIAL EMBOLISM.

IN another column we publish the record of a case of mitral stenosis complicated with embolism of six main arteries. The patient was admitted into the St. Marylebone Infirmary suffering from cardiac disease and bronchitis. At first he improved under treatment and was able to be up all day. Suddenly symptoms of collapse developed, accompanied by severe pain in the legs and abdomen, paralysis of both lower limbs and of the left arm, and loss of sensation in both legs. Some of these symptoms abated but death ensued in the course of 24 hours. At the post-mortem examination there was well-marked constriction of the mitral valve with recent vegetations on the wall of the left auricle. Embolism of the following arteries was found: both common femorals, the right internal iliac at its bifurcation, the right renal at its division, the superior mesenteric just below the middle colic branch, and the left brachial at the origin of the superior profunda branch. Embolism as a complication of mitral stenosis is a fairly common phenomenon, and the arteries of the brain and of the kidneys are those most usually affected. Next in order of frequency are pluggings of the splenic arteries, and occasionally the arteries of the pancreas, the stomach, and the intestines are found blocked by emboli. In cases in which acute endocarditis, especially infective endocarditis, has supervened, the limitation of the emboli to the viscera is not so decided, for peripheral arteries may then be affected, more particularly the posterior tibial, brachial, and popliteal. The number of large vessels involved in the case recorded by Mr. R. S. Roper is of considerable interest, more especially as the cerebral vessels seem to have escaped altogether. Pulmonary infarcts are also not uncommon in cases of infective endocarditis, but in this instance they did not occur. It would have been interesting to have obtained a bacteriological examination of the recent vegetations in the left auricle, although in the clinical course of the case there was nothing to suggest that the endocarditis was of an infectious nature.

SCHOOL TRAINING FOR HOME DUTIES OF WOMEN.

AT the recent meeting of the British Association for the Advancement of Science Professor Arthur Smithells, F.R.S., read a very interesting paper upon the subject of the training of women while still at school for home duties. He pointed out that in a number of homes it is impossible for the mothers to teach the children since the mothers have no knowledge, and even if they had the knowledge the children have to go out to work. In a different class of the community, where it might be thought that girls could be trained at home in matters regarding the management of the home, the training of the daughters cannot be properly carried out on account of the "ignorance, prejudice, and folly" of the domestic circle. Professor Smithells thinks, and we think with him, that a great deal of simple instruction in the elements of the household arts, and in the inculcation of clean and orderly habits of living, should be given at school, and he laid special stress upon the teaching of science. He alluded to many of the common phrases in use in a household as evidence of an absolutely unscientific attitude. The common phrases, "It has gone wrong," "The jelly won't set," "The meat won't keep," and "The fire won't draw" make up the language of superstition, for a demon of perversity is implied behind them, the true cause of the troubles being unknown. And here he pointed out how many schoolmistresses who have taken high degrees in science can give no intelligible account of the reasons why certain things happen, or do not happen, in a house—they do not know, for example, why washing soda "goes white or why brass goes green." We are in full sympathy with Professor Smithells's contention that even the most elementary scientific knowledge is absent from most of our households; every medical man must have noticed the fact. We are glad, therefore, to learn that he has found it possible to arrange a course of science lessons in which scientific discipline and scientific method can be inculcated by simple experimental work, based entirely on matters of the household and of daily life; "where," to use his own words, "the information acquired is truly useful knowledge; and where the minds of the pupils are awakened to the fact that the household is a laboratory of applied science." The way of the wife and mother of the future, to say nothing of that of the husband, would be rendered more easy if the home could be worked upon the lines suggested.

COLOURED URINE.

THE *Edinburgh Medical Journal* for June contains a useful article by Dr. W. Murrell and Dr. Wilson Hake on the various causes of abnormal colouration of the urine. In the majority of cases of blue or green urine the colour is due to the administration of methylene blue. A green colour may result from admixture of the methylene blue with the normal yellow colouring matter of the urine. Green urine may also be due to biliverdin, which may be easily recognised by its characteristic tests. In a small minority of cases blue or green urine is due to other causes, and although most of these are well known, a summary of them is of value and interest. Indigo-blue urine is rare; large quantities of indigo may be taken without affecting the urine. The indigo found in urine is formed from indican, a normal constituent and a derivative of indol, a product of intestinal digestion, and, of course, the quantity of indican in the urine is increased in cases of obstruction of the small intestine. Indican in the urine may also be due to the administration of certain drugs, such as creasote or turpentine. On oxidation indican readily splits up into indigo blue and potassium hydrogen sulphate. Urine containing indigo blue is always alkaline and usually in a state of decomposition. Black or dark urine may be due to several causes. In carboluria the urine is dark when passed or it becomes dark on exposure to air from the formation of hydroquinone. The colour is usually olive-green but may be smoky. Fuchsine, when administered in small doses, from one-half to one grain thrice daily, may also produce olive-green urine. In melanuria the urine is of the colour of *café-au-lait*. This condition occurs in malarial cachexia, in melanotic affections of the skin and liver, and after the ingestion of certain drugs, such as creasote and turpentine. On addition of nitric acid the urine becomes black from conversion of the chromogen of melanin into that substance. In hæmoglobinuria and hæmatoporphyrinuria the urine is of a port-wine colour. The latter condition occurs in sulphonal and trional poisoning. Excluding febrile urine loaded with urates and urine containing blood in quantity, red or purple urine may be due to the administration of a number of drugs. After taking the synthetic purgative "purgen" (dihydroxyl-phthalo-phenone) the urine is not coloured if acid but shows a deep crimson-red colour if alkaline. This colour is destroyed by acids and restored by alkalies. Purgatin (anthrapurpurin diacetate) colours the urine bright red. Pyoktanin or methyl-violet may impart its colour to the urine. Fuchsine, a derivative of aniline, produces a bright purple urine in doses of from one grain to three grains; in smaller doses, as already mentioned, the colour may be olive-green.

ACCIDENTS TO JOCKEYS.

WE have previously[1] drawn attention to the deficient care taken at many racecourses to insure prompt medical attention when accidents occur. A recent instance serves once more to emphasise the need of which we spoke. Accidents of one sort or another are almost necessarily of frequent occurrence at race meetings, and it seems to us a pity from every point of view that some adequate arrangement is not arrived at in every important racing centre between the authorities and the local medical profession. On the part of the latter, at any rate, we are certain that there would be every readiness to provide for the attendance of proper medical skill, so that the unfortunate victims of accident need incur no added danger from delay or from hurried, improvised, and ignorant assistance. The accidents that befall jockeys are often of just such a nature that their immediate skilled treatment plays an all-important part in determining the eventual favourable result. For often subsequent difficulties are met with and comparatively bad results obtained because the golden moments for proper treatment in the first instance were wasted through the non-appearance of the necessary surgical skill.

BACILLUS VIOLARIUS ACETONICUS: A NEW MICROBE PRODUCING ACETONE.

M. L. Bréaudat has described in the *Comptes Rendus* of June 5th, p. 1280, a new microbe which is capable of producing acetone at the expense of proteid matter. It is a chromogenic (violet) organism, colourless, oval in shape, and is readily stained by aniline colours though not by Gram's method. It was discovered in drinking water at

---

[1] THE LANCET, April 15th, 1905, p. 1015.

Saigon in Cochin China. Its most important property consists in the power of producing acetone in a solution of peptone. It is a facultative aerobic organism, developing at temperatures between 30° and 37° C. and producing spores on about the sixth day. It liquefies gelatin, reduces nitrates to nitrites without disengagement of gas, and coagulates milk. It has received the name bacillus violarius acetonicus.

THE APOTHECARY'S SYMBOLS.

OF thousands of medical men who daily write prescriptions probably very few know the origin of the signs of the apothecaries' table as they are written. The ignorance is excusable, for these signs can only be traced in the tangle of the abbreviations and contractions of mediæval MSS. There were more than 5000 contractions of Latin words in use in France between the seventh and sixteenth centuries, and more than 1000 are found in official documents in England during the Tudor period alone; in comparison, Chinese is almost simple. On account of the costliness of writing materials and the labour of transcription abbreviations and contractions were a necessity. The Romans, with the direct boldness which was a characteristic of their race, simply left out whole syllables of words in inscriptions and writings, but the mediæval clerk had not this courage. He essayed a conventional code of expression for the most frequent syllables. The commonest syllable in mediæval Latin was the termination "us." This was abbreviated in early cursive MSS. into ψ̇ which is the long ſ with a flat U written over it. In the rapid writing of the commoner volumes this sign degenerated into the two dots representing the top and bottom of the ſ which left a sign similar to our colon (:); thus m: came to represent "mus" and b: to represent "bus." This kind of expression for a contracted syllable is known by palæographists as a "ligature" and other ligatures were in frequent use. For a long period the contraction symbol ; (our semicolon) was one of those standing for "et," the dot representing e and the comma standing for the slurred remains of the cursive t. This semicolon came gradually to be written ʒ, which we can readily see is only a hasty, careless method of writing a semicolon without raising the pen. And we must remember that to raise a reed pen in rapid writing risked a blot, and blots were not favourably received in mediæval scriptoria. For a long period again this ligature (ʒ or ;) was confined to words ending in que or et, as in qnʒ for *quandoque*, quʒ for *quoque*, āʒ for *apparet*, oʒ for *oportet*, l; for *licet*, tʒ for *tenet*, and s; for *scilicet*. Afterwards the symbol was generalised to signify the omission of any final syllable, so that oʒ came to mean *ounce* or *uncia*. When printed text arose the ʒ at once became a z to suit the convenience of a limited fount of type, but before this change became general the symbol oʒ had been slurred by hasty writing into ℥ and the lower weight of the drachma was derived from this as ʒ. The sign for the scruple ℈ is a "ligature" for sr, the long ſ being crossed by a cursive r.

THE COST OF VACCINATION.

OUR readers may remember that in the House of Commons on May 23rd Mr. John Johnson asked the President of the Local Government Board whether he had power by himself to reduce the fees paid to public vaccinators without having to appeal to Parliament or any other authority, and, if so, whether he would arrange for such reduction. Mr. Burns said in reply: "The Local Government Board is empowered in its own discretion to make rules and regulations with respect to the remuneration of public vaccinators. I am giving consideration to the regulations on this subject." We now understand that Mr. Burns has intimated that the regulations for the charges of vaccination will be dealt with by an order of the Local Government Board at some time in the autumn. This statement may foreshadow a reduction in the fees paid to public vaccinators, and those to whom such a reduction seems just should remember that the Vaccination Act of 1898 laid a large amount of extra work on the shoulders of these officials. The public vaccinator now has to visit the child's house and to perform the operation with special precautions. He has more clerical work to do than before and two or more statutory visits are required. Naturally, even under the minimum scale of fees, the cost of vaccination increased, and ever since the Act of 1898 came into force boards of guardians have been complaining all over the country of the great cost of vaccination. It may be that the system of vaccination in general will be transferred from the guardians of the poor to the public health authorities, but although some public vaccinators may earn their fees easily, others, especially in country districts, have to do an enormous amount of work for a very small fee, and may even be out of pocket through their vaccination work.

ELECTROLYTIC DISINFECTANT.

ATTENTION was first drawn to the peculiar nature of the powerful antiseptic action of partially electrolysed sea water in a series of bacteriological experiments made by THE LANCET Special Analytical Sanitary Commission in connexion with the Hermite process of sewage treatment by electricity which was tried on a small scale at Worthing in 1893.[1] It was shown that in the case of the bacillus typhosus the action of the electrolysed saline fluid was reduced to one half or less of its previous disinfecting power up to the first five or ten minutes of its operation, but, on the other hand, its efficiency seemed after this time to be not merely recovered in the stronger but even in the weaker solutions. It is probable, therefore, that the chlorine bodies formed some passing combination with the medium by which these substances acted as a carrier, so that the antiseptic was handed on again in an even more efficient form to the micro-organisms. A similar action takes place on adding the antiseptic to urine—that is to say, the antiseptic value tested in five minutes is reduced to about one-half on the addition of urine; but the antiseptic power which seems to have been lost, if it is given sufficient time to operate, is still available, as in 24 hours the solution with urine exerts the same influence as that without. It, in fact, seems more active. Samples of broth which had received comparatively small quantities of electrolysed saline solution even after several weeks contained a sufficient amount of available chlorine to be titrated in the form of iodine with arsenious acid or thiosulphate of soda. These experiments seem to us to account for the extraordinary disinfecting and deodorising power of electrolysed salt water. Putrid meat or fish offal, for example, is most effectually deodorised when immersed in the electrolysed fluid. There can be little doubt, however, that it is of the utmost importance that the electrolysed saline fluid should be permanent as regards its strength, as represented in terms of available chlorine. Unless attention is paid to certain details during the production of electrolytic fluid in the electrolysers, and to its treatment immediately after its output, the fluid will gradually lose its strength. Since describing the interesting installation at Poplar in THE LANCET of March 24th, 1906, p. 852, many improvements in a practical direction have been made, so that not only is an active antiseptic fluid turned out continuously and needing little attention, but one which keeps at a standard strength and is permanent. The solution used contains magnesium chloride and sodium chloride. Magnesium chloride used alone does not give satisfactory results, while it more readily furnishes active chlorine compounds than the sodium salt. The solution is made faintly alkaline with caustic soda so as to prevent the formation and escape of free chlorine in the cells. The electric current is governed automatically in order to give constant results and to avoid overheating. The stability of the newly electrolysed fluid is secured by the addition of a proper quantity of caustic soda. At the Poplar installation a paddle with rubber flaps is rotated in the fluid at the moment when it leaves the electrolysers, and it is intimately mixed with some caustic soda solution. The resulting solution shows no loss of strength. It is probable that this procedure results in the formation of a double hypochlorite of magnesium and sodium which, unlike the corresponding salt of magnesium, is quite stable. The process is extremely simple and the plant requires only a minimum of attention, the output of the disinfecting fluid, constant in strength, being perfectly regular and continuous. Mr. F. W. Alexander, the medical officer of health of the borough of Poplar, has devoted considerable energy and time to reducing the installation to a thoroughly practical concern, with the satisfactory result that the plant works with complete smoothness. It is capable of turning out an almost unlimited volume of efficient disinfectant by merely supplying a saline fluid and switching on the current. In time of epidemic such an installation should be invaluable.

---

[1] THE LANCET, May 26th, 1894, p. 1321.

OFFICIAL DISBURSEMENTS OF COUNTY MEDICAL OFFICERS OF HEALTH.

FROM the extent of the area under his supervision a county medical officer of health may have to pay a considerable sum in the course of a year as travelling expenses, and the labour involved in official correspondence and the preparation of reports makes the assistance of a clerk almost indispensable. The details of petty finance involved in such matters, and in the general management of an office, can be easily shown in an account-book by anyone who has received a mercantile training, but to keep such books and to make cash in hand or overdrawn agree exactly with the balance of debit and credit columns is not proper employment for an official whose chief responsibility is connected with the limitation or prevention of infectious disease. There are, indeed, many able men to whom such minor duties are positively distasteful. An obvious solution of the difficulty is for the county council to allow the medical officer a definite sum in commutation of his expenses, based on the average of several recent years, and we are glad to learn that the Surrey county council has just taken this course in respect to Dr. Edward C. Seaton, who has been the county medical officer for over 15 years. In bringing the subject before the council preparatory to the consideration of it at the meeting held on July 31st Dr. Seaton mentioned among other details that the Income tax Commissioners had for a long time allowed a deduction of £85 from the amount of his salary prior to assessment. At the meeting of July 31st the council decided to commute Dr Seaton's necessary working expenses for an annual sum of £150, an arrangement which must be satisfactory to a busy man whose congenial subjects are sanitary science and epidemiology.

CONGENITAL ABNORMALITIES IN THE ABDOMEN.

MALFORMATIONS in the abdomen are not rare, and this is only what we should expect when we consider the large number of organs which it contains. Probably the most common of all is Meckel's diverticulum, but there are many other forms. In the "Mirror of Hospital Practice" in the present issue of THE LANCET we print an account of a case in which two abnormalities were found in the abdomen of a boy, five years old. A cyst was found attached to the pylorus, lying between the mucous and muscular coats and of a size sufficient to cause some obstruction. It contained some clear serous fluid. So far as we are aware cysts have not hitherto been described in this situation. The only suggestion we can make is that it may have been a barren hydatid cyst. In the same case was found an excessive development of a fold of peritoneum which has been called the "sacro-genital fold." It was so well marked as to be palpable per rectum. It does not appear, however, that it interfered definitely with the passage of fæces. Both of the conditions deserve to be put on record and their coincidence is remarkable.

HOMICIDE OR SUICIDE.

AN inquest held recently at Alford, Lincolnshire, respecting the death of a widow named Ann Powell, aged 69 years, recalls in certain measure two cases of death from mechanical violence followed by burning of the body which will always figure as *causes célèbres* in the annals of forensic medicine. Reference is here made to the Peasenhall and Norwich tragedies. The deceased woman, who lived alone, was undoubtedly the subject of delusional insanity. She was last seen alive about 10 P.M. on July 9th. At 9 A.M. on the following day smoke was seen issuing from her bedroom window. On the house being entered it was found that the furniture and other articles were scattered about in great confusion. A basket of clothes and some cooking utensils had been put outside the back door. The body was discovered in a sitting posture against the wall at the foot of the bed. A chopper with a hook, such as is used for cutting gorse, was found under her left thigh. The instrument was the property of the deceased. The only clothing on the body unconsumed by the fire was on the left arm, and that was burning. The day clothes were on the bed, and by the side of it there was a bloody skirt, and blood was on the pillow. A folding chair with blood on it was also on the bed. The bedstead at the foot was covered with blood. There was a piece of newspaper on a chair with blood and hair on it. The pictures had all been taken from the walls. A ladder by which there was access from the kitchen to the bedroom showed blood marks on the steps, as if made by naked feet. According to the police evidence the marks looked as though someone had been up and down the ladder. There was no proof that a robbery had been intended or committed. Mr. W. F. Dale, a surgeon at Alford, saw the body shortly after the discovery of the tragedy. He found the soles of the feet and palms of the hands covered with blood. There were no wounds on the hands or feet. He described the fatal injuries as follows: "At the back of the head there was a wound one and a half inches by two and a half inches and the scalp was pulped for about half an inch round. The skull was shattered and a portion driven into the brain in small pieces. There was a second wound one inch above and to the right of the other. There was a clot of blood between the scalp and the *left* frontal bone one and a half by one inch." The fracture of the skull at the site of the larger wound was the only injury of importance bearing on the question of homicide or suicide. The entire thickness of the bone had been cut in a slanting direction from below up and from left to right, beginning at the occipital protuberance. The divided surface of bone was coarsely grooved, showing that the blow had been delivered with a dull cutting instrument such as the chopper above referred to. Moreover, the upper end of the chopper exactly fitted the cleft of the bone. Either by reason of the bluntness of the instrument or by a wrenching action following on the initial blow the bone beyond was broken irregularly through. Mr. Dale was of opinion that there was no evidence of return foot-marks on the stairs, and the marks were not smeared at the edges. These facts are at variance with the deposition of the police officer. Mr. Dale calculated that death had taken place from one and a half to two hours before the discovery was made. If this be correct it seems clear that the deceased could not have placed herself in the position in which her body was found, because no great amount of clothing had been consumed. An accidental fall of an unconscious or semi-conscious person into the sitting posture is highly improbable, especially as the body retained the position. Again, although a large quantity of blood had been lost from the scalp wounds, there was only the mark of blood where the head rested against the wall. None had trickled down it. Judging from recorded cases we must concede the possibility of a person with head injuries such as the deceased had received setting herself on fire or even going up and down stairs. Opposed to the theory of murder are the following facts. No robbery had taken place; no person would benefit materially by the death; blood stains were absent from the doors and windows and floor of the front room; the age of the deceased negatived a common motive for murder; and the position of the house, situated between and adjoining other houses in the main street would not make a murderous attack safe. Against this collective evidence, which the coroner's jury deemed sufficient to justify a judgment of "Death from suicide," was there sufficient to warrant one of two alternatives—homicide or an open verdict? We are of opinion there was. Mr. Dale, supported by his colleague, Dr. Thomas Edward Sandall, was positive that the injury to the skull could not have been self-inflicted. We have had the opportunity of examining the bone and we feel constrained to endorse their opinion. Apart from the position of the injury, suggestive at least of homicide, we have the facts that the bone was cut through at the thickest part of the skull; that it was done by a very dull instrument, as shown by the grooving of the sectional surface; that very great force must have been used, such probably as a woman, 69 years of age, would find it difficult to exert; and lastly, the direction in which the blow was given, from below up and from right to left. The coroner referred to the medical evidence given in the Camberley case as bearing upon the elucidation of the facts before him. In that case, he said, the medical man, although stating that the wounds on Miss Hogg's body were strongly suggestive of homicide, was of opinion that the theory of suicide could not be excluded. The quotation was correct but if the nature, site, and direction of the wounds had also been borne in mind he would have at once seen there was no parallel between the two cases. By practically ignoring Mr. Dale's testimony the jury, in our opinion, put themselves in an unenviable position, for should further evidence arise pointing to a different verdict it would be seen that their finding had, to say the least, tended to discourage continued investigation. On highly technical matters jurors should admit that they are justified in accepting the judgment of those best qualified to speak with authority. Moreover, if such judgment should ultimately prove to be erroneous the jury would be absolved from the charge of hasty or ill-considered reasoning.

SANITATION IN BERMONDSEY.

AT the recent quarterly meeting of the Bermondsey Municipal Association a discussion took place as to the advisability of discontinuing the practice of burning the refuse of the district in view of the great cost of running the destructor. The sanitary advantages of the system of cremating refuse were strongly advocated by Alderman Wilkinson, who was, however, met by some extraordinary arguments from the chairman, Mr. Hugh Colin Smith. This gentleman appears to have proclaimed a belief that street refuse when accumulated was a desirable adjunct to a neighbourhood or, at all events, to have said that the sorting of it, usual when it is not burnt, was a healthy occupation, because 100 years ago "all the great physicians used to prescribe for the ladies of the West-end who suffered from weak lungs a course of visits to the dust heaps of London, to stand over them and breathe the effluvia, because the gases emitted from decaying vegetable matter strengthened the chest." Mr. Hugh Colin Smith, if he desires to revert to the medical and sanitary methods of 100 years ago in the conduct of his own household, is quite welcome to do so as long as he does not thereby bring himself into collision with the law. He will, however, hardly find them applicable to the somewhat augmented population and changed conditions of life observable in Bermondsey since the early part of the last century, and we should recommend him to leave anecdote alone and to concentrate his attention, and that of the association over which he presides, upon bringing about the working of the destructor in question more economically rather than upon doing away with it altogether. The dust heaps to which he referred would by now have grown to mountains of respectable size had their augmentation been allowed to continue, but they would hardly have taken the place of the Highlands or of the Alps as a touring ground for those in search of a healthy holiday.

Colonel Kenneth Macleod, I.M.S., LL.D., honorary physician to the King, will deliver the address at the opening of the winter session of the London School of Tropical Medicine on Oct. 8th, when the Duke of Marlborough, the President of the society, will occupy the chair.

MEDICINE AND THE LAW.

Disinfection of Infected Clothing.

THE question of the powers and duties of sanitary authorities in regard to articles which have been exposed to infection and also of the liability of authorities who have ordered such articles to be destroyed or disinfected is one of considerable importance. The statutory provisions as to the disinfection of clothing, bedding, &c., are to be found in Section 120 of the Public Health Act, 1875, and Sections 5 and 6 of the Infectious Diseases (Prevention) Act, 1890 (if such sections have been adopted for the particular district). The first paragraph of Section 120 provides that "where any local authority are of opinion upon the certificate of their medical officer of health or of any other legally qualified medical practitioner" that any house or articles therein should be infected, "it shall be the duty of such authority to give notice in writing to the owner or occupier" requiring him to disinfect. In each case the authority must exercise its discretion upon the consideration of the certificate and the notice to the owner or occupier must be given by the authority itself and not by an officer upon his own initiative. If an officer does give such a notice it would seem that the authority cannot ratify it and that it will not support a summons for non-compliance (see St. Leonard's, Shoreditch, v. Holmes, 50 J.P. 132). In practice the result is most inconvenient and calculated to defeat the whole object of the section, for in cases of infection immediate action is necessary, yet nothing can be done until the next meeting of the authority. The last paragraph of the section provides that where the owner or occupier is "unable in the opinion of the local authority to carry out the requirements of this section such authority may, without enforcing such requirements on such owner or occupier, with his consent, cleanse and disinfect such house or part thereof or articles, and defray the expenses thereof." Upon this paragraph a question arises as to whether or not a previous notice in writing (based upon a certificate) is necessary; at the time the point is immaterial, for if an officer of the council in fact obtains the owner's consent, the clothing will be disinfected; but should injury be done to the clothing in the process of disinfection, as must frequently be the case, the answer to this question may have an important bearing upon the right of the owner to recover compensation in respect of such injury. The case of Foster *v.* East Westmorland Rural District Council (68 J. P. 103) was one which raised a point of some interest as to the liability of a sanitary authority under Section 120 of the Public Health Act, 1875, in respect of articles damaged and destroyed by its officers in the process of disinfection. The plaintiff brought his action upon an award for £25 0*s.* 8*d.*, and the case was (by consent) argued upon a statement of facts found for the purpose by the umpire. It appeared that on Jan. 15th small-pox broke out in the plaintiff's house at B., and his medical attendant duly notified the fact. Thereupon the sanitary inspector went to the house and the question of disinfecting and destroying clothes, &c., was discussed between him and the plaintiff, the latter saying that he should expect compensation. Under the advice of the medical officer of health the patients were removed to the hospital, and on Jan. 20th the inspector's deputy attended and disinfected some articles and destroyed others, carrying out the work in accordance with written instructions previously given to him by the medical officer of health who had visited the house. Some of the articles so disinfected were damaged but it was not suggested that the damage was otherwise than unavoidable. The medical officer of health had given no certificate under Section 120 nor had any written notice been served upon the plaintiff under that section, but it was found as a fact that such notice would have been served had the plaintiff objected to the disinfection and destruction, but that he agreed because he thought he would be compensated. In addition to the articles above referred to other articles, the property of the plaintiff at O., were destroyed without his consent or knowledge. The umpire awarded £1 10*s.* for articles damaged in disinfection; £4 10*s.* for articles destroyed at B.; £9 for articles destroyed at O.; £5 5*s.* costs of arbitration; and £4 15*s.* 8*d* costs of award. This award was affirmed by the county-court judge, who held that where the authority itself disinfects with the owner's consent no previous notice in writing is necessary; that the medical officer was therefore carrying out the provisions of the statute; and that as the authority had adopted, or, at least, not disavowed, his acts, it must pay compensation. The practical difficulty in the efficient working of Section 120 of the Act of 1875, which has been referred to, is remedied by Section 5 of the Infectious Diseases (Prevention) Act, 1890, and wherever that section is adopted it supersedes Section 120. Under this section it is no longer necessary for the authority to consider any particular case; as soon as the necessary certificate is given the clerk must act upon it by serving the required notice. The section enacts as follows:—"(1) Where the medical officer of health of any local authority, or any other registered medical practitioner, certifies that the cleansing and disinfecting of any house, or part thereof, and of any articles therein likely to retain infection, would tend to prevent or check infectious disease, the clerk to the local authority shall give notice in writing to the owner or occupier of such house or part thereof that the same and any such articles therein will be cleansed and disinfected by the local authority at the cost of such owner or occupier unless he informs the local authority within 24 hours from the receipt of the notice that he will cleanse and disinfect the house or part thereof and any such articles therein to the satisfaction of the medical officer of health within a time fixed in the notice. (2) If within 24 hours from the receipt of the notice the person to whom the notice is given does not inform the local authority, or if, having so informed the local authority, he fails to have the house or part thereof and any such articles disinfected within the time fixed in the notice, the house or part thereof and articles shall be cleansed and disinfected by the officers of the local authority under the superintendence of the medical officer of health, and the expenses incurred may be recovered from the owner or occupier in a summary manner. (3) Provided that where the owner or occupier of any such house or part thereof is unable, in the opinion of the local authority or of their medical officer of health, effectually to cleanse and disinfect such house or part thereof and any articles therein likely to retain infection, the same may without any such notice being given, but with the consent of such owner or occupier, be cleansed and disinfected by the officers of, and at the cost of, the local authority." It will be noticed that in this clause the medical officer of health is expressly empowered to judge of the owner's ability to disinfect property. Section 6 also intrusts further discretion to the medical officer and allows him (if armed with a general authority to that effect) to require bedding, &c., to be handed over for disinfection at the cost of the authority. The Act of 1890 contains no general compensation clause and is not directed to be read as one with the Public Health Act, 1875. It seems, therefore, that if articles are damaged whilst being disinfected by the authority under Section 5 no compensation will be payable in respect of unavoidable damage and the remedy for unnecessary damage will be an action for negligence. Where, however, they are removed for disinfection under Section 6 it is expressly provided that compensation is to be paid in respect of unnecessary damage, the amount being settled by a court of summary jurisdiction. In Garlick *v.* Knottingley Urban District Council (68 J. P. 494) it was held that where articles which have been exposed to infection from any dangerous infectious disorder were destroyed by an inspector of nuisances acting on the order of the medical officer of health without express direction from, or ratification by, the urban authority, the owner of the articles has no claim for compensation against the urban authority under Sections 121 or 308 of the Act of 1875. The only provision under which an authority can destroy infected bedding or clothing is contained in Section 121 of the Act of 1875. The section does not require any certificate or notice, but merely says that the "authority may direct the destruction of bedding, clothing," &c. The result is that in the event of an outbreak of serious infectious disorder a medical officer is placed in a very difficult position; if, in the exercise of his own discretion, he orders the destruction of infected bedding he may find the authority refuse to approve his act, in which case he may be liable to an action for trespass, whilst if he must wait until the next meeting much mischief may be done. It is desirable, therefore, that a medical officer should obtain a general authority to direct the destruction of infected articles, at any rate in cases of serious illness such as small-pox.

"*Refreshing the Memory*" *in Court.*

The extent to which notes may be read by a witness under examination in a court of law with a view to refreshing his memory was raised lately and in a somewhat novel manner in the case of Holden *v.* the Prudential Life Insurance Company of America. A medical man was called as a witness. He stated that although he had examined the deceased man some years previously and in fact had in his hand a note taken at the time of that examination he had quite forgotten the patient and his particular circumstances. The testimony of this witness was objected to, an objection which the court of first instance allowed; on appeal, however, the Supreme Judicial Court of Massachusetts held that the medical witness should have been permitted to refresh his memory as to the facts of the case in question. This case must be compared with the decision in the Supreme Court of New York in 1904, that a nurse could not produce a clinical chart, regularly filled in, to prove the physical condition of a patient formerly under her care. It may be stated generally that it is far preferable for a witness to get up his evidence thoroughly before he submits to a public examination, and not to refer to notes during that ordeal; there is always a suspicion, when reading from alleged records, that the other side is employing a potent fallacy common to every species of real evidence; thus the witness seems to say: "This fact must be true. Here's my note. I made it at the time." Before contemporary records are allowed by a judge, and admitted to aid the memory of a medical witness, certain conditions must be fulfilled. The private note or memorandum which it is proposed to read must be sworn to be the original record and not a clean copy made for the purpose of the present examination in court; it must have been made contemporaneously with the event to which it refers and by the witness himself as soon after the clinical or post-mortem examination as possible; its reception rests with the presiding judge to allow or disallow. The notes quoted are open to the inspection of the court; since 1824 they have to this extent been a sort of exhibit. Only so much of the note as the witness refers to, however, can be inspected and commented upon by the court. Mr. Gladstone used to say: "The best memory is a record made at the time," and it behoves all medical men who may willy-nilly have to give medico-legal evidence to have at hand a full note as to what was discovered or advised when an examination was made of a person who figures later as a litigant, either personally or by his representatives.

Sketching Witnesses in Court.

The announcement has been made that in the Probate, Admiralty, and Divorce Division the practice of making drawings of witnesses, which afterwards figure as illustrations to newspaper reports of the trial, must be discontinued. The order of Sir John Gorell Barnes will be welcomed by none more than by medical witnesses, who come into court as a rule unwillingly and can feel nothing but annoyance at seeing ridiculous travesties of their features figuring often in very objectionable company, and usually in connexion with cases the unpleasant characteristics of which constitute their principal claim to public attention. The present regulation is confined to the division named, but it may set an example to be followed elsewhere. That it is needed is shown by the wide circulation which has been given to statements that in the court where the inquiry was held into the mental condition of the Marquis Townshend an artist actually *set up a canvas* with a view to the production of a large painting of the scene, that cameras were used, and that the paint brush as well as the pencil was employed in more than one instance. After this we might expect before long a pause in the hearing of a trial in a badly lighted court for the taking of a flash light picture such as we are familiar with at public dinners. The making of these sketches is an innovation which has arisen and increased with the modern craze for publicity in private matters and with the misguided enterprise of certain journalism; but those whose memories go back but a little way can recall how the late Mr. Justice Denman, a most dignified judge, and one with strong views on the decencies of life, forbade an artist to draw a witness in a *cause célèbre* arising out of the theft of a pearl. Many portraits of witnesses and accused persons have been drawn since then, and in many instances the mere fact of being sketched as well as stared at in a crowded court must have added to the discomfort and hardship endured by an unwilling victim. There is only this to be said for the practice—that the publication of the portraits of witnesses or of persons charged with offences may sometimes lead to results beneficial to the cause of justice by making their identity more easily recognised than would the mere publication of names which are possibly assumed. Against this must be set the badness of the likenesses which must render such desirable recognition of even less frequent occurrence than it would be otherwise, and also the distress and annoyance caused in the majority of cases without any possibility of compensating advantage. To members of the medical profession called as witnesses the annoyance must always be considerable, and, as we have observed, they will welcome the prohibition.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 16th, 1828.

POISONING BY PRUSSIC ACID.

The attention of the public in this country has recently been directed to the subject of poisoning by Prussic Acid, in consequence of the suicide of a condemned felon, by this means; and, in France, at the present moment there is much excitation on the same subject, from the occurrence of a most lamentable catastrophe in one of the public hospitals; no less than SEVEN patients having been poisoned by the incautious use of it. .... The account which has reached us, respecting the death of seven patients by prussic acid, in one of the French hospitals, (*Bicêtre*), is as follows:—M. Ferrus, one of the physicians, was in the habit of employing prussic acid in cases of epilepsy; and the formula which he used was that of Magendie, under the title of syrup of hydrocyanic acid, consisting of one part of medicinal prussic acid to 128 of syrup. In private practice, the medicine had always been procured at the shop of M. Pelletier, and an ounce was usually prescribed for a dose. M. Ferrus, wishing to try the medicine in the hospital, ordered it in the dose of an ounce to fourteen epileptic patients. The house surgeon represented to M. Ferrus, that drachm doses only were given, and that these occasionally produced unpleasant symptoms. This induced M. Ferrus to prescribe half an ounce, although he had, as before stated, usually directed half an ounce to his patients in private practice. The medicine was procured from the *Pharmacien Centrale des Hopitaux*, where the syrup is prepared according to the *Codex*, or French Pharmacopœia, which is, one part of prussic acid to nine parts of syrup. The Infirmary man commenced the exhibition on the 14 epileptics; by the time he had given it to the seventh the first was dead, and the others expired in the course of twenty minutes. Magendie uses the acid prepared according to the formula of Gay-Lussac; he adds six times its volume, or 8·5 times its weight of distilled water, and he then designated it medicinal prussic acid. The acid directed in the French Pharmacopœia, is prepared according to the process of Scheele, which, in the opinion of Magendie, is exceedingly uncertain in its results. The formula of Gay-Lussac, or of Vauquelin, should always be followed. Mr. Garden, of Oxford Street, prepares it according to Vauquelin; it is made at Apothecaries' Hall by Scheele's process.

HARDENING OF STEEL BY A CURRENT OF COMPRESSED AIR.

From the observation of travellers, that the manufacture of Damascus blades was carried on only during the time when north winds occurred, M. Anozoff made experiments on the hardening of steel instruments by putting them, when heated, into a powerful current of air, instead of quenching them in water. From the experiments already made, he expects ultimate success. He finds that, for very sharp-edged instruments, this method is much better than the ordinary one; that the colder the air and the more rapid the stream, the greater is the effect. The effect varies with the thickness of the mass to be hardened. The method succeeds well with case-hardened goods.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Liverpool.—The history of the sanitary advancement of the city of Liverpool is one of the most interesting in existence and the short account which Dr. E. W. Hope furnishes in his current annual report of the sanitary condition of Liverpool in the earlier part of the nineteenth century is one which must make the present citizens on the banks of the Mersey thankful that they were born a generation or more later. In 1841 the population of Liverpool was 223,000 (it is now 733,714) and of this number some 160,000 belonged to the working classes. Of these latter more than a third lived in courts and cellars, the courts being connected with the street by a passage or archway about three feet wide. The houses themselves were back to back and side to side, having no yards or open spaces at the sides or rear. As regards the cellars they were from 10 to 12 feet square, generally flagged but frequently having only the bare earth for a floor, the cellars being sometimes less than six feet in height. There was frequently no window, so that light and air could gain access to the cellar only by the door, the top of which was often no higher than the level of the street; consequently the cellars were dark and ventilation was out of the question. There was sometimes a back cellar used as a sleeping compartment and having no direct communication with the external atmosphere, deriving its scanty supply of light and air solely from the door of the front apartment. A population of over 20,000 inhabited these cellars and the whole of this population was without out-offices or places of deposit for their refuse matter. Speaking of the lodging-houses, Dr. Hope tells us, apparently on the authority of Dr. Duncan, who was health officer of the city for so many years, that in every room except the kitchen and common rooms the floor was covered with bedsteads, each of which received at night as many human beings as could be crowded into it, and this, too, often without distinction of sex or regard to decency. As to the cellars, Dr. Duncan himself said: "The floor of these cellars, often the bare earth, is covered with straw, and there the lodgers, all who can afford to pay 1*d.* for the accommodation, range themselves as best they may until scarcely a single available inch of space is left unoccupied."

The water-supply in 1845 was such that fires were frequently uncontrolled and the two water companies charged arrears due from a former tenant to the new one. "Large numbers of courts were destitute of water, the supply having been cut off for non-payment, and the inhabitants had no other water to use from year's end to year's end except what they begged or stole from their neighbours." Under these conditions we are but little surprised to read of fights and squabbles among the people in their efforts to get their vessels filled with water. From a report of Mr. Riddall Wood who investigated the state of education in the Liverpool of this time, it appears that the schools were dark and confined, damp and dirty and used as dwelling and dormitory by the teacher's family. 40 of these were cellars. Under these conditions typhus fever thrived and 1 person in 25 of the working-class population was annually attacked by this disease. And before the Liverpool Sanitary Act of 1846 had been brought into effective operation there came the potato famine of Ireland and by June, 1847, some 300,000 destitute Irish emigrants had landed in Liverpool. Many of these were transmigrants but some 80,000 filed into the lodging-houses and forced their way into cellars which had been closed under the Health Act of 1842. Typhus fever prevailed and ere long "the epidemic burst through the barrier which had hitherto seemed to confine it to the poorer classes of the inhabitants. …… In one street, Lace-street, no less than 472 persons died from it and other causes during the year, being one-third of the entire population of the street." In 1849 cholera was introduced by emigrants, and in the course of that year 7000 deaths were ascribed to it and allied diseases. Dr. Hope, in describing the introduction of cholera by emigrants in 1866, quotes from Dr. Trench a vivid description of an Irish wake over the body of a woman dead from cholera. Dr. Trench was unable to procure speedy burial and after detailing the wake he adds: "There had been in the presence of death one of those shameful carousals which, to the disgrace of the enlightened progress and advanced civilisation of the nineteenth century, still linger as dregs of ancient manners among funeral customs. It was a rash challenge to the dreaded pestilence; and how and with what fearful results accepted the mortality returns of the next four months will too clearly show. Suffice it now to mention that before the period of a week had passed John Boyle, the husband of the woman, was also among the dead, and before the end of July 48 persons had died from cholera within a radius of 150 yards from the court which had been the scene of the ill-timed revelry." This writing of Dr. Trench reminds us rather of the pen of Sir John Simon, and the whole of Dr. Hope's retrospect makes admirable reading. It is indeed regrettable that there is no more of it and we would suggest its expansion with copious footnotes and references and its publication as a separate volume. It would serve to awaken the public to the change which sanitary science has wrought, not only in Liverpool but elsewhere.

The City of Birmingham.—In his current annual report Dr. John Robertson speaks well of the drinking water recently introduced into Birmingham from Rhyader in Wales. The water is still somewhat peaty at times but this drawback is gradually diminishing; in reaction the water is not acid but faintly alkaline, and its action on lead pipes only manifests itself when the water is allowed to remain in a new lead pipe overnight. In order to prevent the kettles used for the water from rusting certain manufacturers galvanised both the inside and outside of such kettles which were sold as "Welsh water kettles." It was discovered, however, that now and again as much as from five to eight grains of zinc per gallon were found in the water, a circumstance which rendered the water quite turbid. It was ascertained, too, that some of the cheaper kettles were lined with a mixture of tin and lead instead of with pure tin, and obviously illness from lead poisoning might result. The voluntary notification of pulmonary tuberculosis was introduced into Birmingham early in 1905, the notifications to be treated as confidential and the usual fees to be paid. Only such cases as are regarded as being in an infectious condition are to be notified and arrangements have been made for the gratuitous examination of sputum at the bacteriological laboratory of the University. Dr. Robertson points out that the cases which most require attention from the sanitary authority are those which occur among the more careless and ignorant of the population, and he thinks that among the middle and upper classes such notifications are not necessary, owing to the fact that the majority of the patients in these classes already receive the necessary instruction.

Willesdon Urban District Council.—Dr. William Butler furnishes a table in his annual report for 1905 giving the results of the examination of the eyesight of 11,838 scholars attending the public elementary schools in Willesden. The vision was tested by the teachers under a scheme embodied in the regulations of the education committee. Among the boys 48·6 per cent. only had normal vision, 40·9 per cent. slightly defective vision, and 10·5 per cent. seriously defective vision. Among the girls 34·5 per cent. had normal vision, 49·3 slightly defective vision, and 16·2 per cent. seriously defective vision. Dr. Butler, referring to the above results, observes that "there is some evidence that a public conscience is being created as to the importance of attending to the vision of the children."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8988 births and 4188 deaths were registered during the week ending August 4th. The annual rate of mortality in these towns, which had been equal to 12·0 and 12·6 per 1000 in the two preceding weeks, further rose to 13·8 per 1000 in the week under notice. During the first five weeks of the quarter the death-rate in these towns has averaged 12·5 per 1000, the rate during the same period being 12·3 in London The lowest death-rates in the 76 towns were 3·0 in West Bromwich, 4·2 in Hornsey, 7·6 in East Ham, 7·9 in Burton-on-Trent, 8·0 in Willesden, 8·1 in Wallasey, and 8·3 in Tottenham; the highest rates were 19·0 in Newport (Mon.), 19·7 in South Shields, 19·8 in Stockton-on-Tees, 20·3 in Rochdale, 20·5 in Wigan, 21·2 in Coventry, 21·4 in Huddersfield, and 26·9 in Bootle. The 4188 deaths in the 76 towns showed an increase of 375 on the number in the previous week, and included 753 which were referred to the principal epidemic diseases, against 361, 424, and 486 in the three preceding weeks; of these 492 resulted from diarrhœa, 108 from measles, 59 from whooping-cough, 43 from diphtheria, 31 from scarlet fever, and 20 from "fever" (principally enteric), but not any from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 2·5 per 1000 in the 76 towns and to 2·6 per 1000 in London. No death from any of these epidemic diseases was registered in Hornsey, Bournemouth, Southampton, Ipswich, Burton-on-Trent, Handsworth, West Bromwich, Grimsby, Wallasey, Warrington, Barrow-in-Furness, Halifax, and Middlesbrough; while they caused death-rates of over 5·0 per 1000 in Leyton, Aston Manor, Bootle, and Huddersfield. The highest death-rates from measles occurred in Salford, Burnley, and Huddersfield; from whooping-cough in Portsmouth, Birkenhead, and Newport (Mon.); and from diarrhœa in West Ham, Leyton, Walsall, Aston Manor, Birkenhead, Bootle, Wigan, Leeds, and Merthyr Tydfil. Diphtheria caused ten deaths in London, four in Liverpool, and two each in Portsmouth, Bristol, Derby, and Hull; scarlet fever caused six deaths in London, five in Sheffield, two in Hanley (Staff.), two in Aston Manor, and two in Manchester; while of the 20 deaths referred to "fever," four belonged to London, two to West Ham, and two to Nottingham. One case of small-pox remained under treatment in the Metropolitan Asylums hospitals on August 4th against numbers declining from 13 to one at the end of the six preceding weeks; no new cases have been admitted during the past six weeks. The number of scarlet fever cases, which had been continuously rising from 2225 to 3048 on the 15 preceding Saturdays, had further risen to 3120. 415 new cases were admitted during the week, against 406, 413, and 408 in the three previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 119, 133, and 101 in the three preceding weeks, rose to 111, and were eight below the corrected average in the corresponding week of the four preceding years 1902–05. The causes of 43, or 1·0 per cent., of the deaths registered in the 76 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner. In 54 of the 76 towns, including West Ham, Bristol, Leicester, Hull, and Newcastle-on-Tyne, no uncertified death was registered; there were six in Birmingham, five in Liverpool and in South Shields, four in London, two each in Nottingham, St. Helens, Salford, Leeds, and Sunderland, and one each in 13 other towns.

In 76 of the largest English towns 7361 births and 4424 deaths were registered during the week ending August 11th. The annual rate of mortality in these towns, which had slowly but steadily increased in the four preceding weeks from 11·7 to 13·8 per 1000, further rose to 14·8 in the week under notice. During the first six weeks of the current quarter the death-rate in these towns has not averaged more than 12·8 per 1000, the rate during the same period being 12·7 in London. The lowest death-rates in the 76 towns last week were 5·6 in Newport (Mon.), 5·9 in Reading, 6·5 in Handsworth and in Wallasey, and 6·6 in Hornsey; the highest death-rates were 20·6 in St. Helens, 21·2 in Salford, 22 0 in Hanley, and 23·0 in West Ham. The 4424 deaths in the 76 towns showed a further increase of 236 upon the low numbers returned in recent weeks, and included 1105 which were referred to the principal epidemic diseases, against numbers increasing from 361 to 753 in the four preceding weeks; of these, 865 resulted from diarrhœa, 103 from measles, 50 from whooping-cough, 39 from diphtheria, 27 from scarlet fever, 20 from "fever" (principally enteric) and one from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 3 6 per 1000 in the 76 towns and to 3·9 in London. No death from any of these epidemic diseases was registered last week in Bournemouth, Tynemouth, Ipswich, Burton-upon-Trent, or King's Norton; while they caused death-rates exceeding 6·0 per 1000 in Salford, Wigan, Norwich, Nottingham, Aston Manor, Birkenhead, and West Ham. The deaths referred to diarrhœa, which had steadily increased in the nine preceding weeks from 50 to 492, further rose last week to 865; the highest annual rates from this disease last week were 5·1 in St. Helens, 6·0 in Wigan, 6·2 in Birkenhead, 6·6 in Nottingham, 7·6 in Aston Manor, and 10·2 in West Ham. The largest proportional fatality of measles occurred in Norwich, Huddersfield, South Shields, Burnley, and Salford; and from whooping cough in Middlesbrough and Birkenhead. Scarlet fever caused ten deaths in London, four in Sheffield, and two in Hanley; and diphtheria 13 in London, three in Salford, and three in Hull. Of the 20 deaths referred to "fever" five were returned in London, three in Liverpool, two in Bradford, and two in Leeds. The fatal case of small-pox occurred in Liverpool. No case of small-pox remained under treatment in the Metropolitan Asylums hospitals on August 11th, against numbers declining from 13 to one at the end of the seven preceding weeks; no new case has been admitted in these hospitals since the end of June. The number of scarlet fever cases under treatment in the Metropolitan Asylums hospitals and in the London Fever Hospital, which had increased in the 16 preceding weeks from 2225 to 3120, had declined to 3051 on Saturday, August 11th; 308 new cases were admitted during the week under notice, against 413, 408, and 415 in the three preceding weeks. The deaths referred to pneumonia and other diseases of the respiratory organs in London, which had been 133, 101, and 111 in the three preceding weeks, were last week 112, and were 12 below the corrected average in the corresponding week of the four preceding years, 1902–05. The causes of 43, or rather less than 1 per cent., of the deaths registered in the 76 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in 59 of the 76 large towns, including Manchester, Bradford, Leeds, and Newcastle-upon-Tyne; the proportion of uncertified causes of death showed, however, a considerable excess in Liverpool, Sheffield, Preston, Gateshead, Blackburn, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 14·3, 13·7, and 14·3 per 1000 in the three preceding weeks, decreased to 11·8 in the week ending August 4th, and was 2·0 per 1000 below the rate in the preceding week in the 76 large English towns. The rates in the eight Scotch towns ranged from 7·2 in Paisley and 8·2 in Leith to 15·1 in Perth and 15·5 in Dundee. The 405 deaths in the eight towns showed a decrease of 84 on the number in the previous week, and included 25 which were referred to diarrhœa, 11 to whooping-cough, eight to measles, four to "fever," one to scarlet fever, and one to diphtheria, but not any to small-pox. In all, 50 deaths resulted from these principal epidemic diseases in the week under notice, against 40 and 55 in the two preceding weeks; they were equal to an annual rate of 1·5 per 1000, which was 1·0 per 1000 below the rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the Scotch towns, which had been 11 and 23 in the two preceding weeks, further rose to 25, of which 18 occurred in Glasgow, four in Edinburgh, and two in Dundee. The 11 fatal cases of whooping-cough agreed with the number in the previous week, and included seven in Glasgow and two in Aberdeen. The eight deaths referred to measles, which had been 12, seven, and six in the three preceding weeks, included five in Edinburgh and three in Glasgow. The four fatal cases of "fever" included two of cerebro-spinal fever, both of which were registered in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 59, 66, and 52 in the three preceding weeks, rose again to 61, and were 13 above the number in the corresponding period of last year. The causes of seven, or 1·7 per cent., of the deaths registered in the eight towns in the week under notice were not certified, the proportion in the 76 large English towns during the same week being only 1·0 per cent.

The annual rate of mortality in eight of the principal Scotch towns, which had been 13·7, 14·3, and 11·8 per 1000 in the three preceding weeks, rose again to 14·0 during the week ending August 11th and was 0·6 below the mean rate in the same week in the 76 English towns. The rates in the eight Scotch towns ranged from 10·2 and 11·4 in Paisley and Leith to 15·2 in Glasgow and in Dundee and 18·1 in Perth. The 481 deaths in the eight towns exceeded the number in the previous week by 76 and included 34 which were referred to diarrhœa, 11 to measles, eight to whooping-cough, six to "fever," three to diphtheria, and one each to scarlet fever and chicken-pox. In all 64 deaths resulted from these principal epidemic diseases in the week under notice, against 55 and 50 in the two preceding weeks; they were equal to an annual rate of 1·9 per 1000, which was 1·7 below the rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the Scotch towns, which had been 11, 23, and 25 in the three preceding weeks, further rose last week to 34, of which 18 occurred in Glasgow, four in Dundee, three in Greenock, and two each in Edinburgh, Leith, and Aberdeen. Of the 11 fatal cases of measles, five occurred in Glasgow and five in Edinburgh; and six of the eight deaths from whooping-cough were returned in Glasgow. The six deaths referred to "fever" included five in Glasgow, all of which were certified as resulting from cerebro-spinal meningitis. Two of the three fatal cases of diphtheria, and the death from chicken-pox were also recorded in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 52 and 61 in the two preceding weeks, further rose to 68, and exceeded by 35 the low number returned in the corresponding week of last year. The causes of four, or rather less than 1 per cent., of the deaths registered during the week were not certified, corresponding with the proportion of uncertified causes of death during the same week in the 76 large English towns; all the four uncertified deaths were returned in Glasgow.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 20·9 and 20·1 in the two preceding weeks, declined further to 16·8 per 1000 during the week ending August 4th. During the five weeks of the present quarter the death-rate has averaged 18·7 per 1000, the rates during the same period being 12·3 in London and 12·7 in Edinburgh. The 122 deaths of Dublin residents during the week under notice showed a decrease of 24 from the number in the preceding week, and included 11 which were referred to diarrhœa, two to whooping-cough, and one to "fever," but not any to small-pox, measles, scarlet fever, or diphtheria. These 14 deaths from the principal epidemic diseases showed a slight decline from the numbers in the preceding week and were equal to an annual rate of 1·9 per 1000, the death-rate from the same diseases being 2·6 in London and 1·8 in Edinburgh. The 11 fatal cases of diarrhœa were one in excess of the number in the previous week. The 122 deaths from all causes in Dublin included 28 of children under one year

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JULY, 1906.

* Including membranous croup

of age and 36 of persons aged 60 years and upwards; both these numbers showed a considerable increase on those returned in the previous week. Four inquest cases and two deaths from violence were registered; and 48, or 39 per cent., of the deaths occurred in public institutions. The causes of three, or 2·5 per cent., of the 122 deaths were not certified either by a registered medical practitioner or by a coroner, the proportion of uncertified deaths in London being 0·3 per cent. and in Edinburgh 1·4 per cent.

The annual death-rate in Dublin, which had been equal to 20·9, 20·1, and 16·8 per 1000 in the three preceding weeks, rose again to 17·3 during the week ending August 11th. During the first six weeks of the current quarter the death-rate in the city averaged 18·5 per 1000, the rates during the same period being 12·7 in London and 12·8 in Edinburgh. The 126 deaths of Dublin residents during the week under notice showed an increase of four upon the number in the previous week, and included ten which were referred to diarrhœa, three to whooping-cough, two to "fever," two to measles, two to diphtheria, and not one either to scarlet fever or small-pox. These 19 deaths from the principal epidemic diseases showed an increase of five upon the number in the previous week, and were equal to an annual rate of 2·8 per 1000, the death-rate from the same diseases being 3·9 in London and 1·4 in Edinburgh. The ten fatal cases of diarrhœa in Dublin were fewer by one than the number in the previous week, while the fatality of other epidemic diseases showed an increase. The deaths of infants showed a considerable further increase last week, whereas those of elderly persons showed a decline. Three inquest cases and three deaths from violence were registered; and 39, or 31 per cent., of the deaths occurred in public institutions. The causes of five, or nearly 4 per cent., of the 126 deaths were not certified either by a registered medical practitioner or by a coroner, while all the causes of death were duly certified in Edinburgh and all but two of the 1352 deaths in London.

VITAL STATISTICS OF LONDON DURING JULY, 1906.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 7·7 per 1000 of the population, estimated at 4,721,217 persons in the middle of the year. In the three preceding months the rates had been 5·9, 6·4, and 7·6 per 1000 respectively. The lowest rates last month were recorded in Kensington, the City of Westminster, St. Marylebone, Stoke Newington, and Holborn; and the highest rates in Hampstead, the City of London, Bethnal Green, Southwark, Deptford, and Greenwich. No cases of small-pox were notified last month, against one, six, and ten in the three preceding months. The Metropolitan Asylums hospitals contained one small-pox patient at the end of last month, against six, five, and 11 at the end of the three preceding months. The prevalence of scarlet fever showed a slight excess in July as compared with the previous month; this disease was proportionally most prevalent in Hampstead, Finsbury, the City of London, Shoreditch, Bethnal Green, Southwark, Deptford, and Greenwich. The Metropolitan Asylums hospitals contained 3004 scarlet fever patients at the end of last month, against 2192, 2462, and 2705 at the end of the three preceding months; the weekly admissions averaged 395, against 282, 321, and 254 in the three preceding months. Diphtheria was considerably more prevalent than in the preceding month; the greatest proportional prevalence of this disease was recorded in Hammersmith, Bethnal Green, Stepney, Bermondsey, Deptford, and Greenwich. The number of diphtheria patients in the Metropolitan Asylums hospitals, which had been 850, 760, and 782 at the end of the three preceding months, had further risen to 872 at the end of last month; the weekly admissions averaged 135, against 103, 98, and 114 in the three preceding months. The prevalence of enteric fever was considerably less than in the preceding month; amongst the various metropolitan boroughs this disease was proportionally most prevalent in Islington, Holborn, Poplar, Southwark, and Greenwich. There were 93 enteric fever patients under treatment in the Metropolitan Asylums hospitals at the end of the three preceding months; the weekly admissions averaged 15, against 11, 12, and 20 in the three preceding months. Erysipelas was proportionally most prevalent in St. Pancras, the City of London, Bethnal Green, Southwark, Bermondsey, and Deptford. The 25 cases of puerperal fever included three belonging to Lambeth, and two each to Fulham, Bethnal Green, Battersea, Wandsworth, and Deptford.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending July 28th 4079 deaths of persons belonging to London were registered, equal to an annual rate of 11·3 per 1000 of the population; in the three preceding months the rates had been 17·0, 13·8, and 11·9 per 1000. The death-rates last month ranged from 8·1 in Stoke Newington, 8·2 in Lewisham, 8·3 in Hampstead, 8·4 in Paddington, and 8·7 in Fulham and in Chelsea, to 13·8 in Holborn, 14·0 in the City of London, 14·3 in Southwark, 14·5 in St. Marylebone, 17·0 in Bermondsey, and 18·1 in Finsbury. The 4079 deaths from all causes in London last month included 482 which were referred to the principal infectious diseases; of these, 126 resulted from measles, 41 from scarlet fever, 41 from diphtheria, 60 from whooping-cough, 25 from "fever" (chiefly enteric), and 189 from diarrhœa. Among the metropolitan boroughs these diseases caused the lowest rates in Paddington, Chelsea, Stoke Newington, Camberwell, Greenwich, Lewisham, and Woolwich; and the highest rates in St. Marylebone, Finsbury, Poplar, Southwark, Bermondsey, and Battersea. The 126 deaths from measles were ten fewer than the corrected average number in the corresponding periods of the four preceding years; this disease was proportionally most fatal in Kensington, St. Marylebone, Holborn, Finsbury, and Poplar. The 41 fatal cases of scarlet fever were seven in excess of the corrected average number; the greatest proportional mortality from this disease occurred in Hampstead, Shoreditch, Southwark, Battersea, Greenwich, and Lewisham. The 41 deaths from diphtheria were seven fewer than the average for the corresponding period of the four preceding years; among the various metropolitan boroughs diphtheria was proportionally most fatal in Hammersmith, St. Marylebone, Finsbury, Bermondsey, Battersea, and Deptford. The 60 fatal cases of whooping-cough showed a decline of 51 from the corrected average number; the highest death-rates from this disease were recorded in Islington, Finsbury, Bermondsey, Battersea and Wandsworth. The 25 deaths from "fever" were six fewer than the average for the corresponding periods of the four preceding years; of these 25 deaths seven belonged to Lambeth, four to Camberwell, three to Islington, two to the City of Westminster, two to Wandsworth, and one each to seven other boroughs. The 169 fatal cases of diarrhœa were 134 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was 30 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 86 per 1000. The lowest rates of infant mortality were recorded in Paddington, Hampstead, Deptford, Greenwich, Lewisham, and Woolwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—*Fleet Surgeons:* G. A. S. Bell to the *President*, additional, for examination of Royal Marine candidates; D'Arcy Harvey to the *President*, additional, for three months' course at West London Hospital. Surgeons: E. A. G. Wilkinson to the *Pembroke*, additional, for disposal (lent to Yarmouth Hospital, temporary). Civil Practitioner S. E. Barrett to be Surgeon and Agent at Tillingham, Bradwell, and Stangate.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Charles J. W. Tatham retires on retired pay (dated August 11th, 1906). Lieutenant-Colonel Robert Caldwell has joined the Southern Command and assumed the duties of Specialist Sanitary Officer, Western area, in place of Major C. J. Willmer Tatham, who has filled that post at Devonport for some time past. Captain Charles S. Cato resigns his commission (dated August 15th, 1906).

Captain R. A. Cunningham has arrived for duty at Gosport. Lieutenant E. G. Anthonisz has left the Southern Command for duty at Colchester.

The Principal Medical Officer in India.

Surgeon-General W. L. Gubbins, C.B., M.V.O., A.M.S., has been appointed to Lord Kitchener's staff as Principal Medical Officer of His Majesty's forces in India, in succession to Sir Thomas Gallwey, K.C.M.G., C.B., transferred to Aldershot.

Imperial Yeomanry.

2nd County of London (Westminster Dragoons): Frederic William Longhurst to be Surgeon-Lieutenant (dated July 16th, 1906). Lothians and Berwickshire: John McWatt (formerly Surgeon-Lieutenant, 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers), to be Surgeon-Lieutenant (dated July 7th, 1906). Suffolk (The Duke of York's Own Loyal Suffolk Hussars): Surgeon-Lieutenant L. A. Avery to be Surgeon-Captain (dated August 15th, 1906). Sussex: Surgeon-Lieutenant J. H. Dauber to be Surgeon-Captain (dated August 15th, 1906).

Volunteer Corps.

Royal Engineers (Volunteers): 2nd (Leeds) Yorkshire (West Riding): Alexander Brodie Seton Stewart to be Surgeon-Lieutenant (dated August 15th, 1906).

Rifle: 1st Lanarkshire Volunteer Rifle Corps: Surgeon-Major F. V. Adams is borne as Supernumerary whilst holding the appointment of Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Scottish Rifle Volunteer Infantry Brigade (dated July 3rd, 1906). 2nd Volunteer Battalion the Oxfordshire Light Infantry: Hubert de Burgho Dwyer to be Surgeon-Lieutenant (dated August 3rd, 1906). 2nd Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Captain and Honorary Surgeon-Major J. H. Maclean resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated August 11th, 1906). 1st Nottinghamshire (Robin Hood) Volunteer Rifle Corps: Surgeon-Captain R. H. Cordeux resigns his commission (dated August 11th, 1906). 2nd Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): Surgeon-Captain E. Farr resigns his commission (dated August 11th, 1906).

Royal Army Medical Corps (Volunteers).

Scottish Command: Edinburgh Company: Lieutenant D. Waterston to be Captain (dated August 11th, 1906).

Deaths in the Services.

Deputy Surgeon-General Henry Fowle Smith, A.M.D. (retired), recently, at the age of 82 years. He joined the army as an assistant surgeon in March, 1847, and having taken the M.D. of the University of Aberdeen in 1850, served throughout the Eastern Campaign of 1854–55, being attached to headquarters. He had medical charge of the staff belonging to the adjutant and quartermaster-general's department, and was subsequently on the personal staff of Sir James Simpson and Sir William Codrington. He was present at the action of Bulganar, at the battles of the Alma, Balaclava, and Inkerman, and throughout the siege of Sebastopol until the fall of the fortress (medal with four clasps, Turkish medal, and the Fifth Class of the Medjidie). In 1867 he was promoted to be surgeon-major. He retired in 1875, with the rank of deputy surgeon-general.

Correspondence.

"Audi alteram partem."

STOMATITIS DUE TO A MERCURIAL INJECTION GIVEN FIVE MONTHS PREVIOUSLY.

To the Editors of THE LANCET.

SIRS,—The case reported by M. P. Menetrier and M. Bouchard and referred to by you in an annotation in THE LANCET of August 11th, p. 386, as exemplifying the dangers of mercurial poisoning by the injection of "grey oil," is the best object-lesson I have yet read to illustrate the results of disregarding one of the first rules followed by the advocates of the intramuscular method—viz., that the mercury must be injected into the muscles and not merely deposited in the subcutaneous tissue. I venture to assert that in the case referred to the poisoning occurred in consequence of faulty technique, as the mercury never reached the muscles at all but, as M. Menetrier and M. Bouchard themselves state, was discovered in the subcutaneous tissue where it had remained temporarily encapsuled.

An injection may fail to be absorbed for many reasons. Firstly, the needle used may not be long enough to reach the muscle through the fatty tissue which is often very plentiful in the gluteal region. Secondly, the needle, though long enough, may not be passed in sufficiently deeply. Thirdly, the locality chosen for the injection may not be a suitable one; for example, if the injection is given too high up in the buttock where the muscular layer is thin absorption is likely to be slow. In a case of my own where injections were given to a stout patient with a short needle, in spite of the fact that several injections had been given the patient's condition did not improve and, a doubt arising as to whether the mercury was being absorbed, a radiograph was taken which showed each dose that had been administered lying in a lump in the subcutaneous tissue. The collections of mercury left by these injections could be both felt in the tissues as nodes and seen in a radiograph for some six weeks afterwards.

In contrast to this a series of radiographs of my patients show that mercury when injected into the muscles themselves spreads out in striæ along the course of the muscular fibres, in which position the looseness of the tissues and their constant state of motion render encapsulation impossible. There is never any node to be felt and a few weeks are always sufficient to obliterate all radiographic evidence of mercury. My assistants and I have pursued this method for over two years, during which time we have had upwards of 200 cases of syphilis under our care in private and hospital practice. Some of these patients have received as many as 40 or 50 injections of grey oil without any ill-effects.

I am, Sirs, yours faithfully,
STOPFORD TAYLOR.

Liverpool, August 14th, 1906.

PS.—A similar explanation might also apply to the cases of mercurial poisoning occurring in the Egyptian command in 1901 and reported in the Army Medical Report of 1904.

THE BELATED LUNACY REPORT.

To the Editors of THE LANCET.

SIRS,—May I draw attention to the fact that the sixtieth annual report of the Lunacy Commissioners is not yet issued? In view of the great increase of lunacy and the projected appointment of a Royal Commission of inquiry may I urge upon the Lord Chancellor—to whom these reports are addressed—to see that the sixtieth report is issued without any further delay than is absolutely necessary? The fifty-ninth report is dated June, 1905. The cost of pauper lunacy for 1904 was £2,286,652; for 1905 this huge sum will be greatly exceeded.

I am, Sirs, yours faithfully,
H. R. GAWEN GOGAY.

Southchurch Beach, Essex, August 11th, 1906.

THE LESSON OF THE PERKIN JUBILEE.

To the Editors of THE LANCET.

SIRS,—Your readers will all be interested in your account of the jubilee of Sir William Henry Perkin, the discoverer of the first aniline dye, but I think it important that the true lesson of this jubilee should be pointed out. There is no gainsaying the fact that the aniline industry was originally an English industry and one we could carry on to the greatest advantage but that to-day the aniline dyes and the other valuable compounds derived from coal tar by synthetic chemistry are made in Germany. The reason for this is not far to seek. If to-morrow a chemist discovered a synthetic process for making quinine at say 1s. an ounce and he took his process to any body of capitalists they undoubtedly would start the works for making the quinine in Germany rather than in England for two reasons: (1) that under the German patent laws a patent is only valid for two years unless the article is made in Germany; and (2) if the works are to be in Germany the manufacturer of 60,000,000 in Germany and 40,000,000 in the British Isles, while if he puts his works down in England he has only 40,000,000 in England, with 60,000,000 in Germany being closed to him by tariff. For the sake of making a fair comparison I have left out of consideration other countries. If I am wrong I should be very glad to be put right by any of your Free Trade readers.

I am, Sirs, yours faithfully.
SIDNEY BARWISE, M.D. Lond., B Sc. Birm.
Duffield, near Derby, August 8th, 1906.

"FLAGELLA OR PSEUDOPODIA?"

To the Editors of THE LANCET.

SIRS,—In Dr. E. H. Hunt's very interesting note *re* the discovery of flagellated protozoa in a rectal abscess caused by the swallowing of a fish-bone, which appeared in THE LANCET of July 28th, p. 216, he states that "the outer coat was very thin and easily protruded when the organism came in contact with pus cells," though he does not seem to connect this property of the amœbæ with the formation of the flagella; he admits that after six hours the flagellated bodies became circular and that the flagella were difficult to see—they had, in fact, disappeared. I need hardly say that these amœbæ, including bacillus coli, have long been known to have the property of protruding pseudopodia in the act of enveloping erythrocytes, &c., a few of which are generally to be found within their endosarcal protoplasm, as shown by the "two or three darker masses seen inside resembling nuclei." The highly refractile ectosarc, extraordinary motility, relatively large size, and the length of their pseudopodia, as compared with those of the bacillus coli, had they been observed, point clearly to their being the entamœba histolytica vel dysenteriæ of Schaudinn.

I would further point out the important fact that these amœbæ are practically extra-corporeal, as noted in my letter to the *British Medical Journal*, dated July 23rd last, and as shown in Dr. Hunt's case their intra-corporeal presence was merely accidental. Regarding the impossibility to detect such protozoa in specimens prepared by any of the ordinary stains, I have always found Romanowsky's stain very satisfactory in distinguishing this protozoon from the bacillus coli; the ectosarc of the latter stains less intensely than the endosarc, while in the entamœba dysenteriæ the ectosarc stains more intensely than the endosarc. There are, of course, many other means of differentiating between the two.

I am, Sirs, yours faithfully,
H. D. McCULLOCH, M.B., C.M. Glasg.,
late Chief Medical Officer to H.H. the Nizam's State Railways Company.
Bournemouth, August 9th, 1906.

SALICYLATE OF SODIUM IN PUERPERAL FEVER.

To the Editors of THE LANCET.

SIRS,—I wish to draw attention to the value of salicylate of sodium in the treatment of puerperal fever. In spite of the utmost care on the part of accoucheurs in disinfecting their hands and instruments septic infection will result in a few cases from various causes, especially among those living in poor and overcrowded districts. A quick pulse with a rise of temperature is an indication of early and active interference, whether this is considered to be due to sepsis or not. A mercurial intra-uterine douche, to be continued twice daily if necessary, and the administration of 10 grains of salicylate of sodium every three hours should soon reduce both the temperature and the pulse. Should there be any depression quinine may be substituted later. I have seen such beneficial results from the use of salicylate of sodium both in puerperal fever and puerperal malarial fever when other remedies have failed that I have no hesitation in recommending it to be tried first of all drugs. Its action is that of an internal antiseptic and together with the local application of an antiseptic douche forms a rational mode of treatment in all cases of puerperal septicæmia. The drug is mentioned in obstetrical works but it does not appear to be used in practice so frequently as it deserves. Its early administration would save the employment of antistreptococcus serum.

I am, Sirs, yours faithfully,
Ealing, W., August 8th, 1906. EDWIN CHILL, M.D. Edin.

STUTTERING.

To the Editors of THE LANCET.

SIRS,—Your issue of July 14th has only just reached me and I crave your indulgence for space in your next issue. Dr. W. S. Colman in his admirable paper does not lay sufficient stress upon the difference between stammering and stuttering, an error commonly made. A stammerer does not know *how* to speak. A stutterer does not know *when* to speak. Stammering is caused frequently, as the author points out, by malformation of the organs of speech, their misuse, &c., whereas the organs in the case of stuttering are perfectly normal and its cause is often cerebral. If accompanied by facial and other muscular twitchings it is more difficult to cure. Medical treatment should go hand in hand with the educational treatment.

I am sure that all concerned in the subject must be grateful to Dr. Colman for having drawn attention to it, for unfortunately we have neglected too long the care and attention of proper articulation in our big public and elementary schools and I hope that very shortly a "Spracharzt" will be attached to all our large educational establishments. We shall have to find a word for the one I use (an importation from Germany), for which I think we have no equivalent as yet in our own language.

I am, Sirs, yours faithfully,
WILLIAM VAN PRAAGH.
Fitzroy square, W., August 10th, 1906.

WHAT IS A SPECIALIST?

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 28th you published a letter with this title signed "A. Z." which appears to me to go insufficiently deep into the matter and to rather understate his case. Your note at the end emboldens me to come to his support, as I firmly and honestly believe you take a rather too charitable view of matters, though your view is the one which I myself held till I experienced what I will relate. I have become disillusioned and write with much bitterness of heart and complete and absolute distrust of all my fellow-men, particularly if belonging to the medical profession, with, of course, a few exceptions. Claiming your motto, "Audi alteram partem," as my justification, I ask you to put before your readers these views and estimations of my fellow men; they have been forced upon me by actual experience of a system of which I and scores of other men are the helpless victims. Incidentally the careers of men are altered by this system and, as "A. Z." puts it, "adversely and profoundly altered"; besides there is the question of helpless wives and children who suffer as the result of a want of organisation and straightforwardness in certain ranks of the medical profession.

A "specialist" as produced by our modern methods is necessarily, I maintain, for a certain number of years a fraud on his profession and the public. He is made a specialist of more or less practical ability by means of public funds subscribed for charitable purposes, the funds being more or less intrusted to the medical profession conjointly with a few lay persons. The *only* person who can be honestly called a specialist from the moment he starts in his specialism is one who has been working at his profession generally, but who, as the result of his work, has taken to a particular subject solely because he is proficient at it; he therefore can, and does, give real value in exchange for the money he demands. The other "specialist" (*sic*) is a person who hopes to become a specialist, who is ignorant of everything in general (not excepting his so-called "specialism") until such time as he has gleaned enough knowledge honestly to deserve to be suspected of "specialism." This person in the meanwhile practises as a "specialist," and not even yourselves can for a moment charitably pretend that the situation even savours of what ought to be. He is, as a rule, some young and lucky man, perhaps with a capacity for making himself agreeable, who has been selected by older men to fill vacancies on hospital staffs. He may even have been selected to keep out other more experienced men, and therefore more dangerous men from a competitive point of view.

Time and professional usages have marred the old ideal that the hospital staff exists for the dispensing of gratuitous care to the poor; the necessity of holding a hospital appointment if a man is to *get on* is now generally recognised. A man must have a post, and if he be a youngster and inexperienced he must have material to gain experience upon. This is well and good, but let us look at the situation honestly. *Incidentally*, the material must be maintained, kept, and fed, and where better than in a hospital and at someone else's expense? Of course, when the rich man who has been paying falls ill he can have the benefit of the special knowledge by buying it at the "ring price." The above fully, though unpalatably, explains the "specialist" business and also his undue multiplication. As we are going, in a few years more there will be far more "specialists" than patients. If appointments are continuously filled by tyros to the exclusion of older and more experienced men the inevitable will happen. A crowd of competitors for public favour will undersell each other. Human nature is the same all the world over, in or out of the medical profession, and the results are the same—a few at the top will busily glean to the last straw, and all the large rest must tumble over one another to get a bare living. The danger to the public may be thought to be not worth considering by some of our colleagues when professional interests are at stake, but I hold that there are all the elements in this "specialist-hospital-system" for a merciless attack on the profession, absolutely unanswerable and overwhelmingly disastrous to the profession as a whole.

I am the last man to pretend that everyonè in the higher ranks of the profession is moulded according to the foregoing picture; indeed, there are men in our ranks to associate with whom is an exhilarating moral and mental tonic. But the good and honest men are too few to leaven the mass below, (I am speaking exclusively of the so-called "specialist"). Two or three grand, noble men can do a great deal in a hospital staff for good; but in the long run it ends the same, as it always does when votes are counted, and here is where the evil shows itself ugliest. The brightest and grandest outlook, but for the constant drudgery and hard work, lies solely in the ranks of the general practitioner, who taking him all in all is the backbone of our calling. To emerge from his ranks and endeavour to enter the so-called higher grade is to take a plunge into a sorry cesspool of human weakness, and that this is so is due to our present system of hospital appointments. I write quite frankly as a disappointed and disgusted man, and I know that this fact must discount my words; none the less I am accurate.

The present system of advertising vacancies, which are not really vacancies in any sense of the term, is a fraud—it puts men to the expense of getting testimonials printed, causes them to worry their friends for these testimonials and wastes their time in calling on medical members of staffs (where one is sure to be told that no one cares a jot for testimonials). You could confer a great boon on your readers if you insisted on obtaining a guarantee that posts really were vacant, and would publish the guarantee along with the notification of vacancy. Why is this trick practised of advertising posts that will be given to selected men for certain, no outsides being wanted? Angry and disappointed candidates will say that it is done simply to fool the public and keep up the flow of money. Who is to contradict them? Calling on staffs in relation to vacancies is one of the most disagreeable things self-respecting members of an honourable profession can be asked to do, and when it is undergone to no purpose in support of a pretence it is loathsome. A man can apply for vacancy after vacancy and be passed over if he has not the reputation of being "a pleasant colleague to work with." All your readers will at once say that they are not surprised, but how many people stop to think what this may mean? The following true story will illustrate my point. I was asked to join a "money Zollverein" on a certain hospital of which I was a new member of the staff. On inquiring what it meant, I was coolly informed that all the members of the "Zollverein" were expected to send their private paying patients to one another for special forms of treatment! I declined to enter into such an arrangement and I was allowed to understand that if I did not I should not be a welcome colleague. Shortly after that, for other reasons, I resigned my post, and now the workers of the Zollverein are, I understand, busy informing members of our profession that they found me most unsatisfactory and quarrelsome to work with.

Candidates for appointments which are really vacant ought to be relieved of the necessity of soliciting the support of persons who do not want to see them. But I would go much further than this. I would place the staffing of the smaller or special London hospitals in the hands of a central body like the King Edward's Hospital Fund, which will look into the credentials of persons willing and desirous of becoming officers on hospitals and will allot a man as vacancies occur. If any man is so allotted, and he is not wanted by the particular hospital staff, let them object formally in writing, stating their grounds, and thus give the candidate the right to meet his accusers. You have invited correspondence and I accept your invitation.

I am, Sirs, yours faithfully,

August 8th, 1906. F.R.C.S. ENG., M.D.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Post-mortem Examinations.

A LETTER appeared in the *Manchester Guardian* about ten days ago narrating the proceedings that took place after the sudden death of a lady, the mother of the writer of the communication to the press. The lady died suddenly, at the age of 74 years, 11 days after her husband's death. The police were informed and police officers called at the house, asked many questions, and at 11.30 P.M. two of them came with orders to take the body to the public mortuary, where a post-mortem examination was made and the coffin was closed without any opportunity being given to the sons and daughters of seeing their mother's face again. So far as can be judged from the letter of complaint to the *Manchester Guardian* there were no suspicious circumstances connected with the death, and the verdict of the jury was "Death from natural causes." It is, of course, difficult to distinguish between cases where such proceedings are necessary and where they may be avoided with safety, but the feeling of the writer in question seems to be that too much is left to the policeman. It is possible that the police in giving their version of the case to the coroner are not always very discriminating, but it would not be well to be lax as to the safeguarding of human life, even if at times some pain is caused. With tact and good feeling it should not often be given.

Small-pox and Scarlet Fever.

Zymotic diseases still assert themselves in this district. At Oldham three householders were summoned the other day for having failed to notify the occurrence of infectious disease in their families. Perhaps the recent outbreak of small-pox has kept the authorities on the *qui vive*. Scarlet fever is prevalent at Hyde. A few days ago there were nearly 80 cases in hospital and the outbreak is described as "of a vicious type and difficult to stamp out."

A Town of Good Counsel.

Blackburn by its health committee gives good advice to its people, young and old. Posters have been displayed setting forth the dangers that alcohol, strong tea, and cigarette smoking bring in their train. "The children of drunken parents are frequently feeble from birth and inherit a direct tendency to many forms of physical and mental disease." The dirt and squalor of the drunkard's home, the children ill-fed, ill-taught, and neglected, his own life drifting from bad to worse, are all told in graphic language which, unfortunately, will be read only by the sober ones. Tea-drinkers are warned against "strong brew" and are told that tea should be freshly made and should only stand about two minutes. By the way, in some parts of the country this "strong brew" is further strengthened by a modicum of rum, tending, as the cronies consider, to good fellowship and the pleasure of drinking. Lastly, the evils of cigarette smoking and the inhalation of the smoke, especially by youths, are given as "potent causes of physical deterioration." Everyone will wish all success to the Blackburn experiment and will hope against hope that the sensible advice of the health committee will meet with the attention of those concerned and be followed by them, but the probability is that the posters will soon be forgotten and covered by others. The old slow method of example and personal influence, well exercised, will turn out to be the most efficient means of checking the mischief of the drink habit.

Ptomaine Poisoning.

An inquest held by the Manchester city coroner on August 9th illustrates the risks people run of ptomaine poisoning and the prevalent ignorance, spoken of already with almost wearisome iteration, as to the proper feeding of infants. A family ate some braised beef which had been bought from a confectioner. The father, mother, and children were all taken ill afterwards and the youngest child, 16 months old, who had, like the rest, eaten this braised beef, died. The confectioner had bought the beef from a butcher on the Thursday. It was cooked immediately and pressed the same evening. On the Saturday evening the last of it was sold to the unfortunate family who suffered so severely, and the confectioner had been told of eight other people who had been made ill. The butcher said that he bought the meat fresh on the Tuesday from the abattoirs, put it in brine, and sold it two days later. On the Saturday evening the beef was eaten, the whole family was ill on the Sunday, and on the Wednesday, in spite of treatment, the baby died. Dr. Scott, who attended them, said that the child died from ptomaine poisoning and that the "poison might exist in an article of food without being discoverable by ordinary individuals." These "cadaveric alkaloids" are of such frequent occurrence and so unsuspected that they should stimulate inquiry as to some method of detection.

Death Certificates.

The city coroner made some strong comments the other day about giving certificates of death. It seems that two students from St. Mary's Hospital attended a confinement and the newly born child died. They could not, of course, give a certificate and the mother's sister was told to go from person to person at the hospital and eventually, it is said, obtained a certificate signed by a medical man, "purporting that the person supplying it was present at the birth." The coroner said that, "as a matter of fact, the doctor was not present and had no business to supply the certificate." The jury gave a verdict of "Death from natural causes." In the absence of further explanation it must be allowed that the coroner was right in his remarks. Although a difficulty as to the death certificate may cause inconvenience to friends, from which a good-natured medical man will wish to relieve them, it does not justify him in going beyond the strict facts of the case and in giving an inaccurate certificate.

August 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Work in Scotland under the Inebriates Acts.

Dr. James C. Dunlop has just issued his report on the work done in Scotland under the Inebriates Acts. At the commencement of the year there were in Scotland six institutions licensed or certified for the treatment or reformation of inebriates. Of these one was a State reformatory, four were certified inebriate reformatories, and one was a licensed retreat. During the year no fresh certificates or licences have been granted, but all the above-mentioned six have continued. The number of persons being dealt with in these institutions, or temporarily absent from them at the commencement of the year, was 107; of these 27 were in a retreat, 47 were in certified inebriate reformatories, 12 were in the State inebriate reformatory, and 21 were temporarily absent from reformatories. Admissions during the year numbered 103, 63 being to a retreat, 36 to certified inebriate reformatories, and nine to the State inebriate reformatory. Discharges during the year numbered 102, of whom 62 were from a retreat, 31 from certified inebriate reformatories, and nine from the State inebriate reformatory. There were transfers from certified inebriate reformatories to the State inebriate reformatory. At the end of the year there were in all 113 persons being dealt with, of whom 28 were in a retreat, 56 were in certified inebriate reformatories, 16 were in the State inebriate reformatory, and 13 were temporarily absent from reformatories. The total number of persons dealt with during the year amounted to 215, of whom 100 were patients in a retreat, 18 were reformatory inmates sentenced under Section 23 of the 1898 Act, and 97 were reformatory inmates sentenced under Section 24 of that Act. As was the case last year, there is in Scotland only one retreat licensed in terms of the Habitual Drunkards Act, 1879, for the reception and treatment of voluntary patients. This retreat, Invernith Lodge, situated in the county of Fife and conducted by Mr. J. Q. Donald, has accommodation for the treatment of 30 inmates and is licensed for the detention of 22 cases admitted in terms of the 1879 Act. Dr. Dunlop states that he visited and inspected this retreat on several occasions during the year and was satisfied that the institution was being conducted in an exemplary manner. It is interesting to note that out of the 185 cases discharged since the opening of this institution it has been possible to trace the subsequent history in 142. Out of these 78, or 55 per cent., have by remaining free from the habit, given evidence of successful issue. To put it more exactly, 45 have been total abstainers for a period of at least a year, while 33 by being abstainers since discharge, though the period elapsed has not amounted to a year, may be considered as hopeful cases. Dr. Dunlop in his report points out that this retreat is only for persons of the moneyed classes, and that there is no licensed accommodation for the voluntary reception and treatment of male inebriates of the poorer classes, and none for the voluntary reception of female inebriates of either the moneyed or the poorer classes.

Appointment to the Chair of Physiology, Glasgow.

The King has been pleased, on the recommendation of the Secretary for Scotland, to appoint Dr. Diarmid Noel Paton, superintendent of the laboratory of the Royal College of Physicians of Edinburgh, to be Regius Professor of Physiology in the University of Glasgow, in place of Professor John Gray McKendrick, who has recently resigned. The new professor of physiology is the eldest son of the late Sir Noel Paton, R.S.A., and was born in 1859. He was educated at Edinburgh Academy and University and also at Vienna and Paris. He was Baxter scholar in natural science in 1882 and biological Fellow of the University of Edinburgh in 1884. He was appointed lecturer on physiology in the School of Medicine of the Royal Colleges, Edinburgh, in 1886, and three years later received the appointment which he will now vacate. He served on the Royal Commission on Salmon Fisheries in 1900. His numerous publications consist mainly of papers on physiological and fishery subjects.

Partick and Cerebro-spinal Meningitis.

At the monthly meeting of the Partick town council held this week Dr. G. A. Brown, medical officer of health, reported that during July four cases of cerebro-spinal meningitis were removed to the hospital. Of the four cases, three occurred in one family and all affected were children. At the next meeting a proposal is to be brought before the council to add this disease for a period of two years to the list of compulsorily notifiable diseases under the Infectious Disease (Notification) Act. As noted in THE LANCET, this measure has already been adopted by the health committee of Glasgow.

August 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University Education in Ireland.

MANY letters have appeared in the morning papers on this subject, especially with reference to the Royal Commission of inquiry which will meet in October. A section of the Roman Catholic laity has expressed its opinion that what is called the "Bonn University scheme" should be considered. It proposes that Trinity College should be reorganised and practically transformed into a mixed college for Protestant and Roman Catholic students. As might have been anticipated, Dr. Walsh, the Roman Catholic Archbishop of Dublin, has written that such a scheme was futile and would only uselessly delay the time occupied by the Commission of inquiry. In a subsequent letter the Archbishop stated that there is "no college within the University of Bonn and therefore there is no college there with two faculties of theology, Roman Catholic and Protestant, with two places of worship; therefore Bonn supplies no precedent for the adoption of the scheme which for brevity was called the proposed Trinity College solution." To this Dr. Rudolf Imelman, Ph.D., who is a member of the teaching staff of the University of Bonn, has replied in a letter in which he states that there is theoretically nothing to prevent the establishment in his university of a college in Bonn where students could live together, Protestant and Roman Catholic. He says, moreover, that he does not follow the Archbishop in what seems to be his conclusion—that the absence of a college in Bonn would make it impossible to apply the Bonn system to the University of Dublin. The proposal really emanated from, and was signed by, 21 Fellows and professors of Trinity College as a scheme for consideration by the Royal Commission about to sit in October but in the light of subsequent events its consideration seems futile. When will Irish University education be settled to the satisfaction of rival religions? The matter is most serious for medical students in Ireland.

Purdysburn Fever Hospital.

On August 10th the Countess of Shaftesbury, at the central fire station, Belfast, named the new motor ambulance, one of two to be used to convey patients to the municipal fever hospital at Purdysburn, "The Shaftesbury." The ambulance is of interest as it is a motor one, with accommodation for two recumbent patients at one time and sitting accommodation inside for two other persons. The ambulance takes the form of a motor brougham, the chassis being 12–14 h.p., of the Cottereau make, fitted with Gaulois tyres, 815 × 100. It has three speeds forward and one reverse speed with ample brake power. At the ceremony the chairman of the public health committee took exception to the medical profession objecting to the location of the hospital at a distance from the city but the inconvenience and discomfort to which the patients would be subjected by being conveyed such a long distance are manifest. The very fact that the public health committee has been obliged to procure motor ambulances to make the transit as short as possible shows how absolutely right the medical profession were in objecting to an infectious diseases hospital being so far from the city. The new motor brougham ambulance takes 17 minutes to go from the central fire station (which is, roughly speaking, about the centre of Belfast) to the infectious diseases hospital, while from many distant parts of the city it will take twice as long a time. However, the essential point is that the hospital, which has been on the *tapis* for many years, will be ready for patients about the middle of September. It will be something to have such an institution at last in Belfast, so that to continue to carp at the site will be churlish.

Belfast District Lunatic Asylum.

At a meeting of the committee of management on August 14th it was decided to approve of the block plan for the villa colony at Purdysburn prepared by Mr. Hine, consulting architect, subject to such modifications as may from time to time be thought necessary, and that Mr. Hine with the local architects should be requested to state the rate of remuneration for plans, specifications, and quantities so as to enable the committee to estimate the approximate cost of the scheme and to decide what particular buildings shall be erected.

August 14th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Malignant Growth of the Stomach; Gastrectomy.

AT a recent meeting of the Rouen Medical Society Dr. Bataille showed a specimen of the pylorus and contiguous half of the stomach presenting on the mucous surface a large circular growth, with thickened and indurated edges, in the centre of which was a deeply ulcerated depression. The growth was obviously malignant. The patient was a woman, aged 37 years, upon whom Dr. Bataille had operated eight years ago for appendicitis. For three months before the second operation she had lost all appetite, had vomited and grown steadily weaker. Through the abdominal walls in the epigastric region and to the right of the middle line there could be felt a hard but mobile mass of about the size of an orange. The mobility allowed the operation of gastrectomy to be possible Some glands were found on both the greater and lesser curvatures. The tumour having been removed, Dr. Bataille sutured the duodenal end to the posterior wall of the stomach, the incision in which he closed by two rows of sutures, practising the operation known as *l'anastomose termino latérale de Kocher*. In a fortnight the patient was convalescent and taking nourishment well.

The French Colonies and the Lunacy Law.

M. Margain and M. Decante have made an interesting report to the Medico-Legal Society of France upon the condition of lunatics in French colonies, the legislative and administrative measures taken in the mother country not being in force in the colonies, where much more arbitrary methods are employed. The number of lunatics in the colonies is relatively larger than it is in France, the most obvious causes being, in addition to the abuse of alcohol and hashish, the presence of many degenerates and persons ill-adapted in other ways to the struggle for existence and many individuals unfortunately influenced by the religious excitement of Mohammedan teaching. M. Margain and M. Decante urge that the same measures as are in force in France should be applied to the colonies, or, failing this, that special means should be devised for putting an end to a lamentable state of affairs. They point out that in Algeria there is no asylum and that the patients have to be transported to Aix or Marseilles.

Mental Confusion in the Course of Typhoid Fever and Scarlet Fever.

At the Sixteenth Congress of Alienists and Neurologists of France held at Lille from August 1st to 7th M. Taty and M. Chaumier gave an account of two cases of mental confusion originating in infectious disease. The patients were two young women, respectively aged 26 years In the one case the febrile period lasted about a month. The patient showed signs of mental agitation and of abhorrence for food. Sero-diagnosis gave a positive reaction for typhoid fever and the patient recovered. In the second case the patient was an alcoholic. Her febrile period lasted some two months. The principal symptoms observed were mental confusion with stupor, abhorrence of food, albuminuria, a parotid abscess, and hæmaturia. The convalescence, during which the mental confusion improved, was hindered by febrile outbreaks due to the abscess. Sero-diagnosis gave a negative reaction as regards typhoid fever. Streptococci were found in the urine and staphylococci in the pus from the abscess. The patient had general desquamation, and apparently scarlet fever was the only infection to explain the morbid train of symptoms.

A New Method for obtaining Hæmatin Crystals for Medico-legal Use.

At a meeting of the Academy of Science held on July 30th M. Sarda and M. Caffart communicated a note about a new method of preparation of hæmatin crystals founded on a method described by M. Leoha-Marzo de Valladolid. The method consists in gently evaporating a portion of the suspected liquid upon a slide; then there are added successively one drop of chlorine water, one drop of pyridin, and one drop of ammonium sulphide The cover-slide is then carefully applied and numerous crystals of chloro-hæmatin are obtained of a rhomboidal form of a deep reddish-brown or scarlet colour.

Loose Bodies in the Knee-joint.

At the summer meeting of the Medical Committee of the Bouches-du-Rhône M. Pons showed loose bodies from the knee-joints of a patient operated upon in the wards under the care of Professor Imbert. The patient was a man, aged 48 years, a miller. One month previously to his operation he suffered from a slight amount of fluid in his left knee-joint following on a fall. At the same time he noticed two moveable bodies in the joint which gave rise to acute pain when he walked. Professor Imbert extracted one of these bodies on May 4th. It was triangular and composed of bone mixed with cartilage. The other foreign body was fixed in the tendon of the patella where it gave the patient no further trouble. Some days later the patient perceived another loose body in the right knee This was removed in the same fashion as the other and the patient went out of the hospital completely cured a few days later.

August 14th.

MEDICINE IN TORONTO.

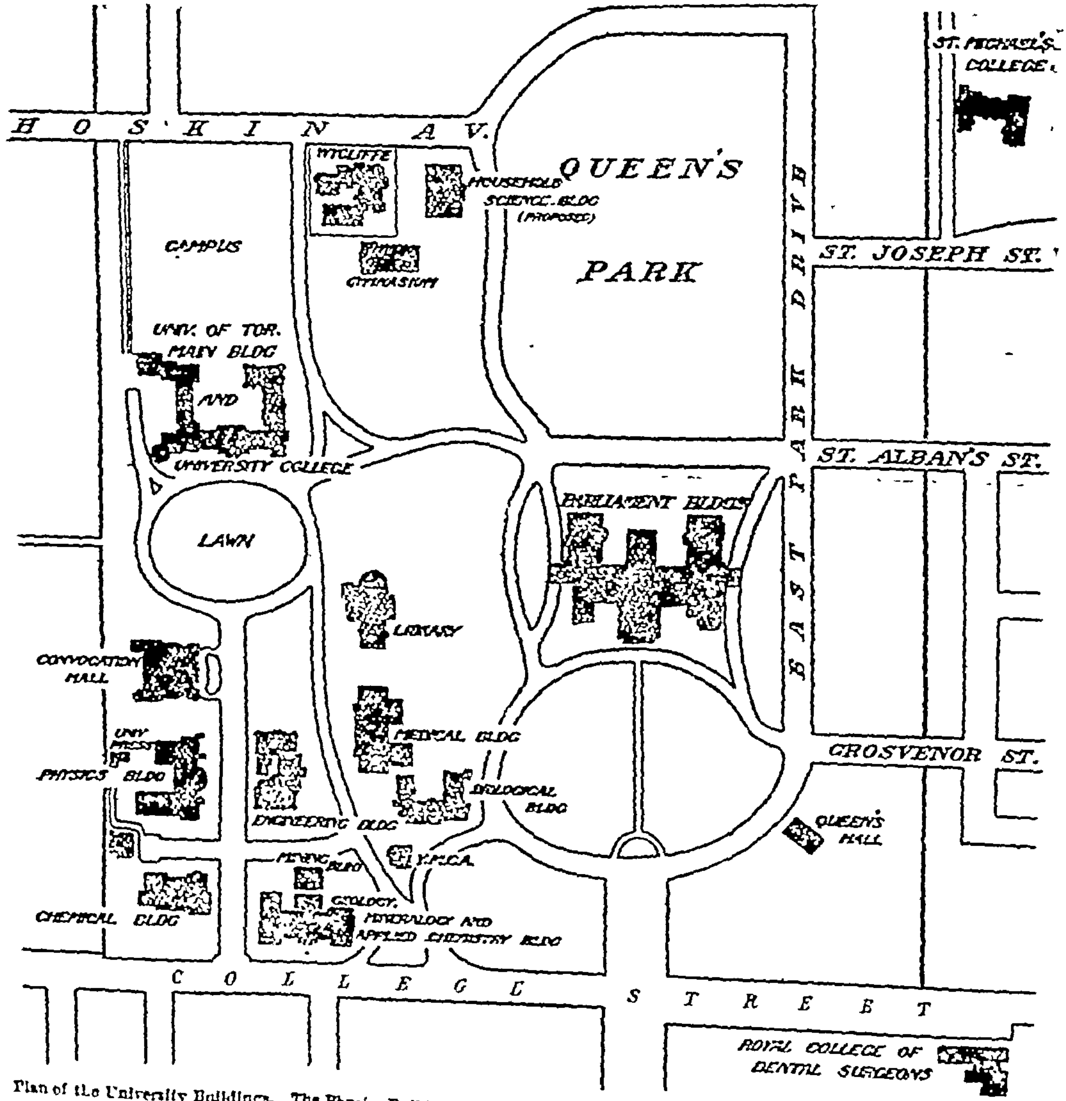
IV.[1]

THE DEVELOPMENT OF THE MEDICAL SCHOOL OF THE UNIVERSITY OF TORONTO AND ITS BUILDINGS.

IT has been shown how, after many checks and drawbacks, in 1887 the Medical Faculty of the University of Toronto came into smooth water. Since that time progress has been more or less uninterrupted. In the place of several medical schools, jealous of each other and so competing among themselves that a low standard of medical education prevailed, there is now *one* central medical faculty which has at its command the best medical talent of the province, as well as the use of buildings for the most part modern, adequate and well equipped for the study of medicine and surgery in their various branches.

The last phase of the fusing of the medical schools of Ontario took place in the summer of 1903, when Trinity Medical School was amalgamated with that of the University of Toronto, and the first inaugural address of the combined faculties was delivered on Oct. 1st, 1903, by Professor William Osler, now Regius Professor of Medicine in the University of Oxford, a Toronto man, and erstwhile a student at Trinity College, Toronto. The present professors in the medical school of the University of Toronto are as follows: Dean of the Faculty: R. A. Reeve, B.A., M.D., LL.D. Emeritus Professors: M. H. Aikins, B.A., M.D., W. W. Ogden, M.D., J. H. Richardson, M.D., and Uzziel Ogden, M.D. Professor and Director of the Anatomical Department: A. Primrose, M.B., C.M. Edin. Professors of Surgery and Clinical Surgery: I. H. Cameron, M.B. Tor., F.R.C.S. Eng., F. Le M. Grasett, M.B., C.M., F.R.C.S. Edin., G. A. Peters, M.B. Tor., F.R.C.S. Eng., and L. Teskey, M.D., C.M. Trin. Professor of Pathology and Bacteriology and Curator of the Museum and Laboratories: J. J. MacKenzie, B.A., M.B. Tor. Professor of Medicine and Clinical Medicine: A. McPhedran, M.B. Tor. Professor of Clinical Medicine: J. L. Davison, B.A. Tor., M.D., C.M. Trin. Professor of Preventive Medicine: C. Sheard, M.D., C.M. Trin. Professor of Materia Medica and Therapeutics: J. M. MacCallum, B.A., M.B. Tor. Professor of Gynæcology and Operative Obstetrics: J. Algernon Temple, M.D., C.M. McGill. Professor of Obstetrics: A. H. Wright, B.A., M.B. Tor. Professor of Gynæcology: J. F. W. Ross, M.B. Tor. Professors of Ophthalmology and Otology: R. A. Reeve, B.A., M.B., LL.D. Tor., G. S. Ryerson, M.D.,

FIG. 13.



Plan of the University Buildings. The Physics Building is in course of erection, while the new Convocation Hall is just completed.

---

[1] Nos. I., II., and III. were published in THE LANCET of July 28th (p. [illegible]) and August 4th (p. 331) and 11th (p. 405), 1906, respectively.

The Medical Building.

C.M. Trin., and G. H. Burnham, M.D. Tor., F.R.C.S. Edin. Professor of Laryngology and Rhinology: G. R. McDonagh, M.D. Tor. Professor of Hygiene: W. H. Ellis, M.A., M.B. Tor. Professor of Medical Jurisprudence: N. A. Powell, M.D., C.M. Trin., M.D. Bellevue, N.Y. Mental Diseases, Extra-Mural Professors: N. H. Beemer, M.B. Tor., and J. C. Mitchell. M.D., C.M. Trin. Professor of Biology: R. Ramsay Wright, M.A., B.Sc. Edin., LL.D. Tor. Professor of Physiology: A. B. Macallum, M.A., M.B. Tor., Ph.D. Johns Hopkins, F.R.S. Professor of Chemistry: W. R. Lang, D.Sc. Glasg. Professor of Physics: James London, M.A., LL.D. Tor.

The buildings in connexion with the Medical Faculty of the University of Toronto can be easily identified upon the subjoined plan, which we have extracted from the latest edition of the University Calendar. The plan omits Annesley Hall, Victoria College, and Knox College, the first two of which lie to the north of Queen's Park and the last some distance to the west. None of the three has any medical bearing whatever. Victoria College, the old Victoria University, now federated with the University of Toronto, is an arts college and is also a theological (Methodist) institution, and Annesley Hall is the women's college in connexion with it. Knox College is a theological college (Presbyterian). The plan (Fig. 13) shows well how the various buildings are grouped around the central building of the University, the University Library, and the Parliament Buildings of this province. The physical laboratory, established in 1878, is situated at present in the western part of the main university buildings and consists of a series of rooms for elementary work, together with a number of special laboratories. But within a short time all these laboratories will be removed to, and occupy, the New Physics Building now in course of erection and shown on the plan.

The psychological laboratory was established in 1892 and is situated in the west wing of the main university building. The laboratory is well equipped for investigations relating to psycho-physics, psychological optics and acoustics, and time relations of mental phenomena. A small library is connected with the laboratory containing periodicals and special literature of experimental psychology. In 1896 the laboratory was enlarged by the addition of the rooms adjoining the ethnological museum and again in 1900 more rooms were added.

FIG. 16.

Professor A. B. Macallum, F.R.S., Ph.D., Professor of Physiology in the University of Toronto.

The biological building, a separate building, is formed of a central portion which contains the biological museum, and east and west wings, the latter of which is chiefly occupied by the anatomical department. The east wing contains the 12 rooms and laboratories of the biological department proper; on the ground floor is a large lecture room which will accommodate more than 250 students. There are also private rooms, a preparation room, departmental library, and a large laboratory for fourth-year students. Above the lecture room on the first floor is situated the elementary laboratory used for the practical instruction of the large classes of first-year students in arts and medicine, while the remainder is occupied by a lecture room for small classes, a laboratory for third-year students, a laboratory for vegetable physiology, and bacteriology and other rooms. The second floor contains two rooms for the preparation and storage of museum specimens, two for the accommodation of live animals, and also two hot-houses for use in connexion with the practical courses in botany. The biological museum occupies the entire central portion of the biological building. Its arrangement is such as to facilitate the most elementary as well as the most advanced studies. The museum is open to the public; its public entrance is approached from the west façade of the biological building. The student's entrance is in the eastern wing, in which the laboratories are situated. The interior of the museum occupies two floors, subdivided into four large rooms, amply lighted and well ventilated. Three of these rooms are devoted to animal biology and the fourth room, which is to be arranged later for the illustration of vegetable biology, is temporarily fitted up for the accommodation of the Ferrier collection of minerals. The north ground floor room, the south ground floor room, and the south first floor room are open to the public and serve the purpose of a well-equipped Natural History Museum.

A serious fire some little time ago wreaked a considerable amount of damage in the buildings of the University, when the biological museum did not escape damage, but fortunately the injuries by fire did not involve the large collection of models and specimens most useful from an educational standpoint, which have been got together at the expense of much money and devoted labour. Private and public generosity has made good to a large extent the losses incurred, and the museum in its existing condition well fulfils the function of an additional source of biological instruction.

The chemical building was completed in 1895. The building comprises two lecture rooms with accommodation for 300 and 100 students respectively, special laboratories for all kinds of chemical analyses, and for the prosecution of original investigation generally.

For some time past the great increase of students had rendered it incumbent upon the University to provide better facilities for their accommodation and more modern and increased methods of instruction and it was formally recognised some five years ago that it would be necessary to provide new laboratories mainly for instruction in final subjects and for pathology and physiology. It was resolved accordingly to erect a building for this purpose in the University grounds. (Fig. 15.) This building, the medical building, was commenced in 1902 and formally opened in October, 1903. It represents a new departure in medical architecture and in consequence is worthy of a somewhat extended description. The buildings were the first to exemplify the unit system of laboratory construction proposed by Professor Minot of Harvard University, although here and there, in consequence of local conditions, it has not been possible to follow Professor Minot's ideals of construction exactly. The main features of this system were described by Professor A. B. Macallum in *Science* of May 22nd, 1903. The laboratory "unit" room must first of all be no larger than is required to accommodate readily the maximum number of students whose practical instruction a single demonstrator can efficiently guide and control. It must also be of such dimensions that it can at need be made to serve as a museum, a library or reading room, or a small lecture room. The units, further, must be so placed with respect to one another, preferably in pairs or series, that by the removal of the partitions separating them rooms of larger dimensions may, when desired, be obtained at a minimum cost and in a short time. The dimensions of such a unit, as determined by Professor Minot, are 23 by 30 feet and this room will accommodate 24 working students, which number experience has shown is the largest that should be under the supervision of a single class demonstrator. Professor Macallum is of the opinion that the system offers the great advantage of elasticity, for a laboratory director may enlarge or contract at will, or according to the needs of the occasion, the accommodation required for a class. It has, he thinks, other and not less important advantages. The cost of construction is less than in any other system, it adequately provides for the all-important question of light, and it permits of subsequent extensions and additions without disturbance of the original arrangements. Professor Macallum also points out that the system provides for the formation of smaller rooms through the division of the unit. This building, which cost £25,000, is situated, as will be seen by reference to the plan (Fig 13), between the University library and the anatomical wing of the biological department. Externally the building presents a somewhat unusual appearance on account of the enormous window space. The window area is 242 square feet, while the outer wall of each unit measures 420 square feet. The window area is therefore almost three-fifths that of the outer wall. The building is three storeys in height in front, with an additional storey and subbasement in the wings, which extend eastward. Two large lecture rooms are provided which flank the main building; the larger has accommodation for about 350 students, the smaller for about 200 students. In the south wing, in what may be called the basement storey, are situated caretaker's quarters, lavatories, recreation rooms, and reading rooms for the students; in a similar storey in the north wing is a large museum of hygiene. The south wing is occupied by the department of physiology and the main portion of the building and the north wing are used by those who are in the final stage of their medical student career. On the ground floor in the main portion are situated in front the dean's room, a large faculty room, a lavatory, and a library, behind which is placed a pathological museum. In the north wing on this floor behind the lecture theatre are a chart and preparation room, preparation and store rooms for the pathological museum, and laboratories for gross pathology. The second and third floors in the same wing and in front contain the laboratories of pathological histology and bacteriology, with rooms for the professor of pathology and demonstrators and "unit" rooms for small special classes. In the north wing on the third floor "units" are occupied by the Provincial Board of Health. The building is heated by air forced over heated coils by large fans driven by steam, and the ventilation is thus in part provided for and also by the exhaust currents in the ventilation turrets which rise over the entrance. A feature of special interest over and above that of the peculiar construction of the building is the provision of special research rooms. The Ethnological Museum is situated in the second storey of the main University building. A large portion of the ethnological collection was destroyed by the fire of 1890, but the museum contains all that was saved from the fire, together with additions which have been made since that time.

FIG. 17.

Dr. A. Primrose, Professor of Anatomy and Director of the Anatomical Department of the University of Toronto.

This has been necessarily a brief and incomplete story of the rise and organisation of medical education in Toronto. But our account does not claim to give more than the outline of all the numerous occurrences—the actions by distinguished individuals, the actions by corporate bodies, the actions by political persons—which have resulted in making of the medical faculty of the University of Toronto an ideally arranged institution for scientific teaching and research. The members of the British Medical Association who have journeyed to Canada will, many of them, still be present in Toronto when this issue of THE LANCET reaches the city. They will have received every facility from the University authorities for studying on the spot the equipment of the medical school, the laboratories, the museums, and all the other buildings to which we have made but passing allusions, and they will bear witness when they return home that we have not employed exaggerated phrases in placing Toronto before the readers of THE LANCET as an admirably appointed medical centre.

THE ANTI-MALARIAL CAMPAIGN IN ITALY IN 1905.

(FROM A ROMAN CORRESPONDENT.)

IN his report of the work done by the Society for the Study of Malaria during 1905, which has recently been published, Professor Celli has to record results from a greater number of stations in Italy than existed in previous years, especially in Southern Italy and in the islands. New and valuable contributions have also again been supplied during the past year by foreign associates. Here are some of the principal conclusions at which Professor Celli arrives after an obviously careful sifting of a good deal of material evidence.

A. Epidemiology.—The epidemic season of 1905 was in general exceptionally mild in the whole of Northern and in a great part of Central Italy. On the other hand, in Latium and Southern Italy (continental portion) it was, as a rule, severe, whilst in the islands it was not quite so severe as usual. A comparison of the incidence of malaria in the different European countries afflicted by it shows that Italy retains an unenviable pre-eminence over all others, the disease being indeed of a graver type in some localities of Southern Italy than anywhere else on the face of the globe. The hæmatological researches prosecuted by some members of the society point to the conclusion that the various parasites in the different febrile forms do not constitute different species but are rather varieties of the same species.

No method has yet been discovered of diagnosing latent infection and recidivous cases, although it is pretty well established that recidivity is one of the chief causes which determine the annual and local variations of malarial epidemics; hence the importance of perfecting the preventive and curative treatment and especially of improving the methods of administering quinine to children. Again, the seasonal variations of epidemics seem to depend more upon biological properties inherent in the respective parasites than upon climatic conditions. Even in the warm climate of Southern Italy we find that anophelism and also rice culture may exist unaccompanied by malaria. It is interesting to learn that the larvæ of anopheles maculipennis in Algeria and of species very closely resembling it in the Dutch East Indies are capable of developing into the mature insect in sea water, even when the latter is concentrated. Should this turn out to be true of the anopheletes along the Italian coast all hope of eradicating malaria from the marshes by flooding them with sea water must be abandoned. The relations between malaria and meteorological conditions become more uncertain and obscure but the earthquakes in Calabria were undoubtedly a predisposing cause of this season's epidemic in that part of the peninsula.

As an instance of the connexion between malaria and certain industries it is noted that among the mining population of Sardinia the epidemic was more severe than among the agricultural population of the same district. Although an undoubted relation subsists between economic conditions and malaria this does not appear sufficient to explain why such terrible outbreaks should occur in Southern Italy and further researches are necessary to clear up the problem.

B. Prophylaxis.—The use of the State quinine goes on increasing in a remarkable way and is accompanied by a corresponding diminution in the mortality from malaria, as may be clearly seen from the subjoined table. An examination of the vital statistics of Italy from 1887 (when the causes of death first began carefully to be registered and analysed) until 1895 reveals an average annual mortality from malaria of over 15,000. From 1895 to 1901 the mortality fell to some extent with, however, the usual periodic recrudescence in 1900. From 1902, on the contrary, when State quinine was first introduced, the mortality diminished rapidly and progressively until in 1905 it reached the lowest figure hitherto attained—viz., 7838. The table also shows the net proceeds of the sale of the State quinine; these proceeds it is intended to apply to purposes having for their object the combating of the disease by prophylactic measures and works of bonification.

Table showing the Sale of State Quinine and the Mortality from Malaria.

Consumption of State quinine.		Mortality from malaria.		Net proceeds of the sale of State quinine.
Financial year.	Kilogrammes sold.	Year.	Total deaths.	
—	—	1895	16,464	—
—	—	1896	14,017	—
—	—	1897	11,947	—
—	—	1898	11,378	—
—	—	1899	10,811	—
—	—	1900	15,865	—
—	—	1901	13,561	—
1902-03	2,242	1902	9,903	34,270 lire.
1903-04	7,234	1903	8,513	183,033 „
1904-05	14,071	1904	8,501	183,382 „
1905-06	18,712	1905	7,838	230,000 „

The exhibition of the drug in the form of "chocolates of tannate of quinine," made by the State Quinine Factory, for rendering it more agreeable to take, especially for children, has proved of the greatest utility, the more so because of the slow rate of absorption of the tannate and its consequent suitability for the prevention of primitive and recidivous infections. For the rapid and radical cure of the "febbri recidive" no remedy has so far been found, the administration of quinine in daily doses of from one gramme to one and a half grammes for months consecutively, with and without arsenic, and by mouth or hypodermically, having failed to extirpate the infection in certain cases. Fortunately the effect of the prophylactic use of quinine for primitive infections is far otherwise. In the "campi dimostrativi" (experimental areas in malarial districts) reported upon by the members of the society, of 59,340 persons thus treated only 3458, or scarcely 5 8 per cent., were affected either by primitive or recidivous infections. The results naturally varied according to the locality and the number of recidivous cases; but even in Southern Italy, where the worst type prevails, the morbidity sank in the first year of the quinine prophylaxis from 35 to 80 down to 18 per cent. In the worst districts the daily dose of quinine should be 60 centigrammes (9 grains) to 80 centigrammes (12 grains), given in the form of bichlorate rather than of bisulphate; where a milder type of malaria prevails a daily dose of 20 centigrammes (3 grains) is sufficient; and where the fever is extremely light it is better to restrict the use of quinine to the inhabitants of houses where a case of primitive or recidivous infection has actually occurred. Mechanical prophylaxis continues to manifest its value. Mixed prophylaxis—i e., a combination of mechanical protection against the anopheletes along with the use of quinine—is, however, now the rule along all the railway lines and is also being adopted largely for the protection of workers engaged in agricultural operations and industrial enterprises in the rural districts. As to exterminating the mosquito, the difficulty, or, rather, in Italy the impossibility, of accomplishing this becomes more than ever obvious.

It is encouraging to learn from this instructive report that, in localities where members of the Society for the Study of Malaria have been working steadily for the last three or four years, the peasants begin to show an eagerness to obtain quinine and, without any incitement being any longer necessary on the part of their medical men, to endeavour of their own accord to protect themselves against malarial infection.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

New Sanitary Regulations.

IN many parts of the country bakers are in the habit of wetting the dough before baking with a sort of broom made of straw or hay. Such straw brooms are likely to contain the germs of actinomyces, and some cases which have occurred make it probable that bread treated in this manner may be the means of transmitting such germs to man. The Minister of the Interior has therefore ordered a closer inspection of bakehouses in rural districts, and a warning has been issued against using brooms of that description for the purpose in question. If for any reason there is no substitute available, the brooms must be sterilised by boiling in water for half an hour and drying in the sun. Remembering the good effects of the leaflets distributed at the time of the epidemics of cerebro-spinal meningitis, the authorities have prepared and distributed in all the provincial bakehouses a similar leaflet describing the symptoms of actinomycosis and the methods of infection. The Minister of the Interior has also caused the regulations concerning the colouring and adulteration of food to be revised, and some colouring materials, such as the aniline dyes which modern chemistry can manufacture free from all admixture of arsenic or lead, will not henceforth be placed on the list of poisonous substances. The official list of colours and dye-stuffs regarded as poisonous now includes substances containing antimony, arsenic, picric acid, mercury, copper, chromium, and lead. Lead is sometimes employed by manufacturers of black silk and hosiery to increase the weight of the fabric, and this metal is frequently present in cosmetic lotions and preparations of that class. Such articles are now liable to be seized if they are intended for human use within the limits of the Austrian Empire.

The University of Vienna.

The medical faculty of the University of Vienna will in a short time lose four of its professors in consequence of the old regulations requiring that all professors and clinical teachers shall retire from their posts on reaching the age of 70 years. Of those who are therefore about to relinquish their chairs, Professor Adam Politzer is perhaps the best known. He will take advantage of the "bonification" permitted by the law, which entitles a professor to occupy his chair for one year more, the so-called "honorary year," after his seventieth birthday, and will accordingly during the session 1906–07 continue his celebrated courses on otology, which are conducted in the English language, if a sufficient number of his audience request it. The other teachers on the point of retiring are Professor Stoffella d'alta Rupe, who does not intend to apply for the honorary year, Professor Winternitz, and Professor Benedikt. Professor Winternitz is the Nestor of modern hydro-therapeutists and to him belongs much of the credit of having given hydrotherapy the position which it holds among modern means of treatment. Professor Benedikt is well known, even beyond German-speaking medical circles, for his investigations on the brain of mammals and for his treatise on the diseases of nerves. An original thinker, he has frequently denounced routine methods in the teaching of medicine and recommended a more individualistic system both in training students and in making appointments to medical posts.

Post-Graduate Study.

The summer term at the University closes at the end of July, but during August and September most of the assistants and several professors who remain in town will deliver post-graduate courses on certain selected subjects. The intention of these classes is to provide practical and theoretical instruction for practitioners who are desirous of keeping themselves informed as to the most recent advances in medicine and surgery, and the classes are naturally held at the time of year when these gentlemen can most easily be away from home. Operations on the abdomen and the genital organs, bacteriology, experimental pathology, and diagnosis are the leading features of the courses, whilst a number of other subjects, such as diphtheria, the use of mirrors, anomalies of refraction, &c., will be lectured upon if sufficient entries are obtained. The fees for such courses, lasting for four weeks, are usually from £2 2*s*. to £4 4*s*., and practical work is facilitated by limiting the number of those admitted to the various classes.

The Annual Report of the Policlinic.

The Policlinic, like the General Hospital, is in various respects under the control of the medical faculty of the University. Its thirty-ninth report dealing with the events of the year 1905 has just been published and contains many interesting details. In 1905 there were 67,000 out-patients and 2247 in-patients, whereas in 1880 there were only 80 in-patients and 12,000 out-patients. During its existence 1,430,000 patients have been treated in both departments. In 1905 there were 119 children admitted to the diphtheria wards and 112 received serum injections. The diphtheria mortality was only 3·3 per cent., which is a great reduction as compared with the results obtained in former years. Previously to 1894 the diphtheria mortality was from 30 to 40 per cent. and the subsequent fall is a convincing proof of the efficacy of serum treatment. By the munificence of very high personages the institution has been able to obtain a considerable quantity of radium bromide, which has been employed chiefly in diseases of the skin and also in the treatment of mucous cancer. Among the in-patients the death-rate was 6 per cent. and among those operated upon it was 9½ per cent., children excluded.

A Series of 1000 Cases of Medullary Anæsthesia.

At a meeting of Croatian practitioners held recently in Vienna Dr. Schwarz read a very interesting paper on the results of 1000 injections of tropacocaine into the spine for surgical purposes. He has for the last four years employed the above-mentioned alkaloid, which gives him better results than either cocaine or stovaine. By very careful attention to the dose, which in no case exceeded 0·06 gramme (= 1 grain), and by taking the precaution of dissolving the alkaloid in ten cubic centimetres of the cerebro-spinal fluid of the patient, he never had a fatal result, and only in very exceptional cases were there any unpleasant after-effects such as nausea, headache, pyrexia, or collapse. The frequency of headache as an after-effect in the experience of previous observers has been explained on the ground that water, even when distilled, has a toxic action on the spinal and cerebral tissue. The modified process in which cerebro-spinal fluid is substituted for water as the solvent of the alkaloid is therefore a great improvement. If the operation was one requiring a long time for its performance Dr. Schwarz elevated the patient's pelvis so that a larger area of the spinal medulla was bathed in the solution. The place of injection was, as usual, between the fourth and fifth lumbar vertebræ. All kinds of operations on the lower half of the body below the umbilicus were performed under this analgesia, only in opening the abdomen the time of analgesia is limited to about one hour; the other parts of the body within the region specified, including the legs, perineum, bladder, and rectum, remain insensitive for two or three hours. Up to the present time about 3000 operations of this kind have been recorded without any fatal result due to the spinal injection.

August 11th.

Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates satisfied the examiners:—

M.S. EXAMINATION.

Thomas Percy Legg, King's College and St. Bartholomew's Hospital; William Paynter Noall, Royal Infirmary, Manchester, and London Hospital; and William Gordon Taylor, B.Sc., Middlesex Hospital.

PRELIMINARY SCIENTIFIC EXAMINATION.

PART I.—INORGANIC CHEMISTRY, EXPERIMENTAL PHYSICS, AND BIOLOGY.

Inorganic Chemistry, Experimental Physics, and Biology.—Thomas Beaton, University College, Cardiff; Sydney Guy Billington, University of Birmingham; Gilbert Alan Blake, Guy's Hospital and University Tutorial College; George Francis Bradley, London Hospital; Gertrude Brooks, London (Royal Free Hospital) School of Medicine for Women; Joseph Henry Campain, University of Liverpool; John Warren Clouston, London Hospital; Gertrude Margaret Dobrashian, London (Royal Free Hospital) School of Medicine for Women; Robert Joel Cazalet Douty, Middlesex Hospital; Basil Franklin Eminson and Ralph Franklin Eminson, Epsom College; David Benjamin Evans, University College, Cardiff; James Maurice Foord, University of Leeds; Abdul Hamid Gool, Guy's Hospital; Alexander Keith Hamilton, University of Liverpool; Reginald Gordon Hill, St. Bartholomew's Hospital; Herbert Leslie Hopkins, Guy's Hospital; Charlotte Leighton Houlton, London (Royal Free Hospital) School of Medicine for Women; Charles Dones Killpack, Guy's Hospital; William Balfour Laird and Martin Wentworth Littlewood, St. Thomas's Hospital; Gerald Roche Lynch, St. Mary's Hospital; Roy Kyffin Mallam, Epsom College; Edith Marjorie Martland, Hulme Grammar School, Oldham; Henry Linnington Martyn, King's College School and private tuition; John Park Mathie, University of Glasgow; Ernest Spencer Miller, University of Liverpool; Stella Myers, Girton College, Cambridge, and London (Royal Free Hospital) School of Medicine for Women; Alfred Arthur Edmund Newth, Epsom College; Joan Fraser Parker, London (Royal Free Hospital) School of Medicine for Women; Sara Louisa Penny, University College, Bristol; James Potter, London Hospital; Thomas William Watkin Powell, Epsom College; Walter Woodall Pratt, University College, Bristol; Ffrangcon Roberts, Epsom College; Douglas Ross and Frederic Sanders, London Hospital; William Henry Price Saunders, Epsom College; Charles Frank Schuler, St. Thomas's Hospital; Emmanuel Prinski Scott, London Hospital; F. R. Bradley Skrimshire, St. Thomas's Hospital; Geoffrey Troughton Smith, Alleyn's School, Dulwich, and Birkbeck College; Reginald Gershom Sparkes, St. Mary's Hospital; Mildred Blanche Stogdon, London (Royal Free Hospital) School of Medicine for Women; Richard Trevor Vivian, Epsom College; Harry Bertram Walker, London Hospital; George Edgar Septimus Ward, Epsom College; Harold Percy Warner, Guy's Hospital; and Roger Michael Wright, University College, Bristol.

Inorganic Chemistry and Experimental Physics.—*Richard Frank Bolt, University College, Bristol; Florence Hilda Bousfield, London (Royal Free Hospital) School of Medicine for Women; Andrew John Chillingworth, St. Bartholomew's Hospital; *Herbert William Cooke, University College, Bristol; Richard Stanley Dowell, University Tutorial College; *Thomas Peters Edwards, St. Bartholomew's Hospital; James Moncrieff Joly, Cheltenham College; Francis Harry Kelly, Middlesex Hospital; Joseph Howell Lloyd, private study; Ernest Mannering Morris, Whitgift School, Croydon; *Camilo Antonio Prada, St. Bartholomew's Hospital; Aneurin Evan Roberts, Towyn County School; Harold Rowntree, Middlesex Hospital; and *John Eric Wood, Hartley University College.

Inorganic Chemistry and Biology.—Albert James Clarke, St Bartholomew's Hospital; ‡John Henry Cobb, University of Sheffield; ‡James Anthony Delmege, Guy's Hospital; Walter Armstrong Elliott, University of St. Andrews; William Reginald FitzHugh, St. Thomas's Hospital; Stuart Leighton Heard, London Hospital; ‡Cyril George Hewett, University College; George Ashby Hooton, St. Bartholomew's Hospital; ‡Harold Arundel Moody, King's College; ‡Alexander George Hains Moore, Guy's Hospital; William Geoffrey Shaw, London Hospital; William Henry Vincent, St. Mary's Hospital; and Godfrey Alan Walker, Epsom College.

Experimental Physics and Biology.—Alured Charles L. O'S. Bilderbeck, St. Bartholomew's Hospital; Frederick Hyland Bowen, Victoria University and private study; Arthur Barrett Cardew, Epsom College; †Herbert Davies, Guy's Hospital, University Tutorial College, and Birkbeck College; Lionel Hugh Knightley Finch, University of Birmingham and Birmingham and Sutton Coldfield Technical Schools; Vincent Glendining, Guy's Hospital; Robert Hamer Hodges, King's College; Gerald Laurence, Epsom College; George FitzPatrick Rigden, King's College and Westminster Hospital; Francis Richard Todd, St. Bartholomew's Hospital; Victor David Collins Wakeford, Birkbeck College; and Harvey Henry Vincent Welch, St. Thomas's Hospital.

Inorganic Chemistry only.—*‡Herbert Stuart Blackmore, University College; George James Bowen and *‡Tudor David Bowen, University College, Cardiff; *‡George Bent Buckley, Victoria University; *‡Noel Hawley M. Burke, King's College; *‡Alfred Bernard Clark, University of Sheffield; *‡Wilfrid M. Glenister, St. Bartholomew's Hospital; Christopher Martin Ingoldby, London Hospital; *‡W. H. Talfourd Jones, Guy's Hospital; John Edward Kitchen, University of Leeds; *‡Geoffrey Marshall, University Tutorial College; *‡Victor Ewings Negus, King's College; *‡Bernard Rayne Parmiter, University College, Nottingham; *‡Ernest Gerald Stanley, St. Bartholomew's Hospital; *‡James Simpson Strachan, private tuition; *‡Ernest Alfred Tozer, London Hospital; *‡Arthur B. Guy Underwood, Birkbeck College; and *Samuel Wilson, Guy's Hospital.

Experimental Physics only.—Gordon Covell, Guy's Hospital; Israel Feldman, City of London School; George Barrowclough Horrocks, Victoria University; Maurice Mackenzie, London Hospital; Percy James Montgomery, Middlesex Hospital; Ralph Herbert Nankivell, Epsom College; *†Ambrose Owen, University College, Cardiff; Herbert T. Retallack-Moloney, City of London School; *Pestanji Manekji Masina, University College; Walter Salisbury, University College, Bristol; *Louis Bruce Stringer, Guy's Hospital; Aubrey William Venables, University Tutorial College; *†Bernard Thomas Verver, Guy's Hospital; and Emily Josephine H. Wallace, The Polytechnic and University Tutorial College.

Biology only.—Carlyle Aldis, Guy's Hospital; John Appleyard, University of Leeds; William Stuart Armitage, St. Mary's Hospital; †‡Margaret Mary Basden, London (Royal Free Hospital) School of Medicine for Women; †‡Cyril Carlyle Beatty, Durham College of Medicine and Armstrong College of Science; †‡Irene Nancy Clough, London (Royal Free Hospital) School of Medicine for Women; ‡Eric Crosby T. Clouston, University College and London Hospital; †‡Eliezer Coplans, University College; †‡Edward G. H. Hood-Barrs, London (Royal Free Hospital) School of Medicine for Women; Edward Leslie Hornburgh and Geoffrey Jefferson, Victoria University; Cecil Augustus Joll, B.Sc., University College, Bristol, and private study; Charles Douglas Kerr, St. Bartholomew's Hospital; Norman Claudius Lake, Plymouth Technical Schools; Peregrine S. B. Langton, Middlesex Hospital; Manly McWhinnie Lopez, University College Bristol; Mary Frances Lucas, London (Royal Free Hospital) School of Medicine for Women; Kenneth D. Marriner, St. Thomas's Hospital; Guy Matthews, King's College; George Martel, Guy's Hospital; Bernard Courtauld Maybury, St. Thomas's Hospital; Mendel Mayers, London Hospital; James Menzies, St. Mary's Hospital; Adrian Leonard Moreton, St. Bartholomew's Hospital; Hannah Grace Morland, London (Royal Free Hospital) School of Medicine for Women; Richard Naunton O. Morgan, University College, Cardiff; Gerald Thomas Mulally, Guy's Hospital; Stella Myers, Girton College, Cambridge; George Edmund E. Nicholls, Victoria University; William Marshall Oakden, Nottingham High School; Henry Brice Parker, University College, Bristol; Willie Howarth Parkinson, Victoria University; William Henry Parr, London Hospital and University Tutorial College; Mary Minnie Patterson and Cicely Mar Peake, London (Royal Free Hospital) School of Medicine for Women; Edward Austen Penny, Guy's Hospital; Wilfred Langrish Pink, St. Thomas's Hospital; Harry Platt, Victoria University; Henry Martin Rashbrook, London Hospital; Morna Lloyd Rawlins and Maude Margaret Richards, London (Royal Free Hospital) School of Medicine for Women; Edward Hesketh Roberts, University College; Arthur Leyland Robinson, University of Liverpool; Cecil John Rogerson, University College; Richard Alun Rowlands, University College Bangor; Mary Schofield, London (Royal Free Hospital) School of Medicine for Women; Clement Edward Shattock, University College; Charles Woolley Shepherd, University College, Cardiff; Bernard Sangster Simmonds, Middlesex Hospital; Elliott John Storer, St. Bartholomew's Hospital; Robert Stout and Thomas Duncan M. Stout, Guy's Hospital; James Simpson Strachan, London Hospital and private tuition; Norman Tattersall, Victoria University; John Bailey Tackaberry, Middlesex Hospital; George Taylor, London Hospital; Leonard Herbert Taylor, Charing Cross Hospital and private study; Gottfried Oram Teichmann, Middlesex Hospital; Graham Yalden Thomson, Guy's Hospital and private tuition; Daniel Owen Twining and Edward Wing Twining, University College; Ernest White, St. Bartholomew's Hospital; Theodore H. Whittington, King's College; and William Wilson Woods, London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

LONGEVITY.—Mrs. Isaac Needs of Brent Knoll celebrated the 100th anniversary of her birthday on July 6th, when she was the recipient of many congratulations.

THE ROYAL SANITARY INSTITUTE.—The forty-second course of lectures and demonstrations for sanitary officers will be held at the Parkes Museum, Margaret-street, Regent-street, London, W., during September, October, and November. The course is divided into two parts. Part I. comprises four lectures on elementary physics and chemistry and 21 lectures on public health statutes, the practical duties of a sanitary inspector, hygiene of communities, and building construction; inspections and demonstrations will also be arranged in connexion with the lectures and will include visits to disinfecting stations, dairy premises, common lodging-houses, refuse and sewage disposal works, and other public and private works illustrative of sanitary practice and administration. Part II. comprises seven lectures on meat and food inspection and practical demonstrations of meat inspection are given. The fee for Part I. is £2 12*s.* 6*d.*, for Part II. £1 1*s.*, or for the complete course £3 3*s.* The tenth course of practical training for meat inspectors will commence on Sept. 21st and will continue for two months. In addition to the practical training at a market the course will include seven lectures delivered at the Parkes Museum. The fee for the complete course will be £3 13*s.* 6*d.* A course of lectures on Hygiene in its Bearing on School Life will commence on Sept. 17th and will continue to Nov. 9th. It will consist of lectures and practical demonstrations on personal hygiene, school buildings, and school equipment. A fee of 5*s.* will be charged for the course. These lectures are intended to assist teachers and others interested in the training of children and the structural conditions of schools. Examinations on various subjects will be held by the institute in London on Dec. 7th, 8th, 14th, and 15th.

BOOKS, ETC., RECEIVED.

APPLETON, SIDNEY, London.

Modern Clinical Medicine. Diseases of Metabolism and of the Blood. Animal Parasites. Toxicology. Edited by Richard C. Cabot, M.D., Instructor in Clinical Medicine in the Medical School of Harvard University. An authorised translation from "Die Deutsche Klinik," under the general editorial supervision of Julius L. Salinger, M.D. Price 21*s.* net.

Diseases of the Nervous System resulting from Accident and Injury. By Pearce Bailey, A.M., M.D., Clinical Lecturer in Neurology, Columbia University, New York City; Consulting Neurologist to the Roosevelt, St. Luke's, and Manhattan State Hospitals, &c. Price 21*s.* net.

A Text-book of Botany. For Secondary Schools. By John M. Coulter, A.M., Ph.D., Head of Department of Botany, the University of Chicago. Price 5*s.* net.

BAILLIÈRE, TINDALL, AND COX, 8, Henrietta-street, Covent-garden, London, W.C.

Applied Bacteriology. An Elementary Handbook for the Use of Students of Hygiene, Medical Officers of Health, and Analysts. Revised and edited by Cressacre G. Moor, M.A. Cantab., F.I.C., formerly Public Analyst for Exeter, and Senior Demonstrator in Public Health, King's College, London, with the coöperation of Richard Tanner Hewlett, M.D., F.R.C.P., D.P.H., Professor of Bacteriology, King's College, London, formerly Bacteriologist to the Lister Institute. Third edition. Price 12*s.* 6*d.* net.

Questions and Answers on Nursing for the St. John Ambulance Associations and Others. By John W. Martin, M.D., of Sheffield, Hon. Acting Medical Officer to the Jessop Hospital for Women, Sheffield; Examiner and Lecturer to the St. John Ambulance Association; Hon. Sec. to the Sheffield Centre. Fifth edition. Seventeenth thousand. Price 1*s.* 6*d.* net.

Aneurysm of the Abdominal Aorta. Being a Dissertation for the Degree of Doctor of Medicine in the University of Oxford. By Frederick Pitcairn Nunneley, D.M., M.A., Brasenose College. Price 3*s.* 6*d.* net.

BLAKELEY, E. H., 11, Adam-street, Strand, London, W.C.

Uterine Fibroids and other Pelvic Tumours. By Bedford Fenwick, M D., Gynæcologist to the Hospital for Women, Soho square; formerly Senior Assistant Physician to the City of London Hospital for Diseases of the Chest. Price 3*s.* 6*d.*

CHURCHILL, J. AND A., 7, Great Marlborough street, London, W.

A Manual of Midwifery. By Thomas Watts Eden, M.D., C.M. Edin., F.R.C.P. Lond.; Assistant Obstetric Physician and Lecturer on Practical Midwifery, Charing Cross Hospital; Physician to Out-patients, Queen Charlotte's Lying-in Hospital; Physician to In-patients, Chelsea Hospital for Women; Examiner in Midwifery and Diseases of Women at the Conjoint Board of the Royal Colleges of Physicians and Surgeons. Price 10*s.* 6*d* net.

A System of Dental Surgery. By the late Sir John Tomes, F.R.S, Corresponding Member of the Philadelphia Academy of Natural Sciences; late Dental Surgeon to the Middlesex and Dental Hospitals. Fifth edition. Revised and enlarged by Charles S. Tomes, M.A., F.R.S; late Lecturer on Dental Anatomy and Physiology to the Royal Dental Hospital of London, and Walter S. Nowell, M.A. Oxon., Assistant Dental Surgeon, Middlesex Hospital. Price 15*s.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BOOTH, LIONEL HETHORN, M.R.C.S. Eng., L R.C P. Lond., has been appointed House Surgeon at the Sunderland Infirmary.

HARRISON, JAMES MCKEAN, M B., B Ch., B.A.O. R U.I., has been appointed Medical Officer to the Workhouse by the Ledbury (Herefordshire) Board of Guardians.

HOLLAND, EARDLEY L., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Resident Medical Officer to Queen Charlotte's Lying in Hospital, London.

LYSTER, ROBERT ARTHUR, M B., Ch.B., B.Sc. Lond., D.P.H., B Sc, has been appointed Medical Officer of Health to the Urban District of Handsworth (Staffs).

MORRISON, J. W H., M.B., B S. Durh, has been appointed Certifying Surgeon under the Factory and Workshop Act for Blaydon-on Tyne District of the county of Durham.

SELLS, H. LANCELOT, M.B., Ch.B. Edin, has been appointed House Surgeon to the Hartlepools Hospital, Hartlepool.

TAGGART, WILLIAM JOHN, M.B., Ch B. Edin, has been appointed Resident Medical Officer to the Victoria Hospital, Burnley.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN CITY DISTRICT LUNACY BOARD, KINGSEAT LUNATIC ASYLUM.—Medical Superintendent. Salary £500 per annum, with house.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Third House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.

BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

BUXTON, DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

CARDIFF, ROYAL HAMADRYAD SEAMEN'S HOSPITAL.—Medical Superintendent. Salary £250 per annum, with residence, firing, and light.

CHESTER GENERAL INFIRMARY.—*House Physician. Salary £90 per* annum, with residence and maintenance.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Senior House Surgeon. Salary £120 per year, with board, apartments, and laundress.

COLCHESTER, ESSEX AND COLCHESTER GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

COTFORD, TAUNTON, SOMERSET AND BATH ASYLUM.—Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, and attendance.

DORCHESTER, COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £140, rising to £180, with board, lodging, &c.

DOVER, ROYAL VICTORIA HOSPITAL.—House Surgeon, unmarried. Salary £100 a year, with board and washing.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House Surgeon. Salary £25 per annum, with board and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Medical Officer for the Casualty Department for six months, renewable. Salary at rate of £100 per annum, with luncheon.

EAST SUFFOLK AND IPSWICH HOSPITAL.—Third House Surgeon. Salary £50 per annum, with board, washing, and residence.

EGYPTIAN GOVERNMENT, MINISTRY OF EDUCATION.—*Professor of Midwifery and Gynæcology.* Salary £400 a year. Also Medical Tutor and Registrar to Kasr-el-Ainy Hospital. Salary £400 a year.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—House Surgeon, unmarried. Salary £120, without board (or £80, with board).

KINGSTON-UPON-HULL, SANATORIUM AND EVAN FRASER (SMALL-POX) HOSPITAL.—Resident Medical Officer, unmarried. Salary £200 per annum, with residence, board, and washing.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—Two House Surgeons and a House Physician. Salary £60 each per annum, with residence and maintenance.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Three House Physicians and One House Surgeon. Salaries at rate of £60 per annum, with board and residence.

LONDON SCHOOL OF TROPICAL MEDICINE.—Craggs' Research Prize, value £50.

LONDONDERRY AND NORTH-WEST OF IRELAND EYE, EAR, AND THROAT HOSPITAL.—Honorary Surgeon.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MIDDLESEX HOSPITAL, W.—Second Assistant to the Director of the Bacteriological and Clinical Laboratories. Salary £100 per annum.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST Hampstead and Northwood.—Resident Medical Officer. Honorarium £50 per annum, including board, lodging, &c.

NORTHAMPTON GENERAL HOSPITAL.—House Physician, unmarried. Salary £90 a year, increasing to £100, with apartments, board, washing, and attendance.

PORTSMOUTH BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, lodging, and washing.

PRESTON ROYAL INFIRMARY.—Resident Medical and Surgical Officer, unmarried. Salary £130, with board, residence, attendance, and washing.

ST. HELENS COUNTY BOROUGH.—Assistant Medical Officer (female). Salary £160 per annum, rising to £200.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta street, Covent Garden, W C.—Junior House Surgeon for six months. Salary at rate of £50 a year, with board, lodging, and washing.

SALISBURY, FISHERTON ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with board, apartments, and washing.

SHIPSTON-ON STOUR UNION.—Medical Officer for the Mickleton District. Salary £50 per annum and fees.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon. Salary £60 per annum, with rooms, board, and washing.

STAFFORDSHIRE COUNTY COUNCIL (Midwives Act, 1902).—Woman Inspector. Salary £120, rising to £150 per annum, with travelling expenses.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at rate of £40 per annum, with board, washing, and residence.

WARRINGTON UNION WORKHOUSE.—Resident Medical Officer, unmarried. Salary £130 per annum, with apartments, rations, and allowances.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.

YORK COUNTY HOSPITAL.—House Physician. Salary £100 per annum, with board, residence, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

FLEMING.—On August 7th, at Chester-street, Edinburgh, the wife of Robert A. Fleming, M.D., F.R C.P. Edin., of a son.

HEDLEY.—On August 14th, at 56, *Hans-place, S.W., to Dr.* and Mrs. Edward Hedley a son.

KENDALL.—On August 10th, at *Chiddingfold, Surrey*, the wife of Nicholas Fletcher Kendall, M.R.C.S., L.R.C.P., *of a daughter.*

SLADEN.—On August 7th, at *Talbot-road*, Highgate, the wife of Reginald J. Lambart Sladen, M.R.C S. L.R.C P., of a son.

WALES.—On August 14th, at Mevell Hall, Gargrave-in Craven, the wife of Herbert Wales M.A., M.B. B.C., of a son.

WICKHAM.—On August 9th at Willesborough, Ashford, Kent, the wife *of* Charles A. Wickham, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

BUCHANAN—HUDSPITH.—On August 11th, at the Church of the Holy Cross, Haltwhistle, Northumberland, Walter Isaac Buchanan, M.B., *to Harriet Louisa*, third daughter of the late County Alderman Hudspith, J.P., and Mrs. Hudspith, of Greencroft, Haltwhistle.

FRASER—JOHNSON.—On August 14th, at Hexham, Lachlan Fraser, M D., *of North* Shields, to Annie, younger daughter of the late John Johnson, Cote House, Blanchland.

SCOTT—SECHERAU.—On August 8th, at St. Mary Abbots, Kensington, Lindley Scott, M.A., M.D, M.R C.P., to the *Baroness Gertrude* von Schmidt Secheran, youngest daughter of Mrs. George Meakin of Creswell Hall, Stafford.

DEATH.

KALAPESI.—On July 16th, at Frere-road, Fort, Bombay, Dr. R. M. Kalapesi, M.B. Lond., *D.T.M.* Camb., M.R.C.S., &c., in his 37th year, of tuberculosis.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

TOUTING AGENCIES.

VARIOUS righteously indignant medical correspondents have forwarded to us the circular which we here reprint:—

THE EBOR EDUCATIONAL AGENCY, YORK.

August 9th, 1906.

DEAR SIR,—A friend of ours has handed your name to us and as we have many doctors in different parts of the country now acting for us we shall be pleased to know if you care to interest yourself in the following suggestion, which can be carried out without any additional trouble or expense to yourself. We are Agents for most of the best private schools in England, also several on the Continent. Our business is to introduce pupils to these schools and our desire is to use the best means possible to find pupils. All we wish you to do is when on your daily rounds to ascertain (in the ordinary course of conversation, without letting the parents think you are interested in the matter) whether they are likely to be sending their sons or daughters away to school and to forward their names to us, together with any other particulars you can give us. *That is all we require you to do.* Your name does not, *in any way*, transpire in the matter, unless in cases where you think it advisable. We then take the matter up and for every pupil we place at a school through your introduction we give you one guinea.

Yours truly,
THE SECRETARY.

The circular is in the usual style of the quack touting pamphlet. There is the unnamed friend who "has handed your name to us." There are also the unnamed "doctors in different parts of the country now acting for us." There is the bribe, in this case only one guinea, whereas in a recent application of the kind we quoted it was three. Modern developments of the commercial spirit reveal an uncomplimentary ignorance on the part of the advertisers as to the status of the medical profession. Sometimes the advertisement wishes the medical man to tout for cigars, sometimes for medicated wines, sometimes for quack medicines which purport to cure anything and everything, and the most disgusting feature of the matter is the habit that the proprietors of these wares have of asserting that they already keep members of the medical profession in their pay. We do not for one moment believe that the Ebor Educational Agency has any medical men acting for it; and the whole tone of the circular is such as to suggest that any parent who employed the agency with regard to the education of his child would be exceedingly foolish.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—Would you be kind enough to adjudicate on the following? A patient X sends for A to attend her. He does so and after a few weeks brings his partner B to see her. Later, the patient requests that C should be called in consultation. C's methods are such that A declines to meet him. A then says that he will meet any other practitioner she likes to suggest. Finally, she selects D who accordingly sees the patient with A. Some weeks later A is about to take his holiday and informs the patient that his partner B will attend her. X then writes to say that she does not wish A to come any more and that she will send for another doctor. Her father approaches D who at first refuses. D is informed that if he does not attend C will be called in. D attends her, and writes to A saying that, when he was informed X desired C's attendance in case of his (D's) refusal, he reluctantly consented. He asked A's approval. A thanked D for his letter but stated that he strongly disapproved of him attending the patient after having seen her in consultation. D, however, continued to attend, and without any further communication to A. Was D justified in his action?

am, Sirs, yours faithfully,
"A."

August 11th, 1906.

*** The situation has been discussed before—indeed, it is a sort of test point in medical ethics. We have in medical ethics to consider the public for whom the medical profession works, as well as the conditions under which that work can best be done. X, as a member of the public, has a right to the advice of whatever medical man she may choose, and no medical man can object to that right being exercised. X was therefore clearly at liberty not to employ A and to make overtures to D. But D was placed in a dilemma thereby. A medical man introduced to a patient by another medical man as a consultant should never, or almost never, continue in attendance on the case. The rule is for the public good. Medical men gladly afford their patients the advantages of consultation, but do so with the understanding that they will not be supplanted. In this instance D was informed that A would, at any rate, lose the patient, and so he considered himself free to attend her. The argument is a strong one, and if D had been a rival practitioner merely it would have been sufficiently strong. But D was, apparently, actually introduced to the patient by A, and should not, we think, have listened to any proposal whatever to take A's place without A's leave. But we cannot understand why A withheld his leave. He was, at any rate, to lose the case, and if D did not attend it the patient proposed to call in C, concerning whom A had taken a very extreme step. For it is most unusual for one medical man to refuse to meet another in consultation. The patient was within her rights to wish to see C, and A could only have denied C's aid to her upon some very good grounds. But if C's methods were likely to be dangerous to the patient while A was by her bedside, how much more dangerous would they be if C were in sole attendance. From that risk D seems to have saved her, and A should not resent it.—ED. L.

THE ACCIDENT ON HANDCROSS HILL.

THE inquest on the bodies of the persons killed in the accident due to the wrecking of a motor omnibus on Handcross Hill on July 12th came to an end on August 7th, when the jury found a verdict of "Accidental death." They also found that the accident was caused by a breakage of machinery brought on by the efforts of the driver to check the speed of the omnibus when he found that he was going too fast and considered that the driver committed an error of judgment in allowing the omnibus to go at too high a speed. They held no one criminally responsible but they were strongly of opinion that this type of omnibus was unsuitable for use on country roads. We think that this is a verdict with which nobody can quarrel, more especially with the last clause of it. Nearly all the motor omnibuses, which are seen about the streets now, have been brought into use while they are still really in an experimental stage, and many of them, owing to the noise the vibration, and the evil-smelling fumes which they emit, are unfit for use on any road of any kind. Two statements made in evidence are worth notice. Mr. William Worby Beaumont, technical adviser to Scotland Yard, in answer to a question by Mr. Morse, who appeared for the Society of Motor Manufacturers and Traders, said that he considered that roads like that of Handcross Hill were extremely unsafe for the traffic of to-day and that there was no excuse for leaving a road in such a state. Mr. Reginald William James, consulting engineer, gave it in his evidence that in his opinion for journeys in country districts where declivities were sharp, emergency brakes entirely independent of the transmission gear were a proper provision for the safety of the passengers. With regard to Mr. Beaumont's evidence, most country roads, in the southern counties at all events, in dry weather are loose and awkward for traffic. We do not think that authorities can be expected to provide roads for the modern motor omnibus, at any rate, for that type of it which is presumably constructed for town use, and is admittedly only constructed in an experimental manner. As to brakes entirely independent of transmission gear, these, to our minds, should be made compulsory upon every description of mechanically propelled vehicle.

MEDICAL ATTENDANCE ON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—Could you give me any information on the subject of fees charged to medical students for professional attendance by qualified medical practitioners? On several occasions when staying in various parts of England I have had to call in a medical man, and although I always ask for the bill to be sent in (as a matter of form as I have now come to consider it), I have never come across any medical man who would allow me to pay him for his services. I know, however, of more than one student who has been charged for professional attendance, and I conclude from this that the question of charging or not is one that each practitioner settles for himself.

I should be very glad if you could tell me if medical students have any *right*, in virtue of their calling, to free medical attendance, or whether it is a case of good nature on the part of most medical practitioners. I inclose my card and remain,

Yours faithfully,
MEDICAL STUDENT.

August 11th, 1906.

*** No one, medical practitioner or medical student alike, has any legal or unassailable right to gratuitous medical advice. Medical men, as a matter of fact, always do treat without charge other medical men and their families, and some medical men extend the privilege to medical students. This is a matter for the individual discretion of the medical man, but the pecuniary circumstances of the student, or his relations to the medical man, generally determine the course to be pursued. There is no reason why a medical practitioner should not charge a medical student, being in a good pecuniary position and a stranger, fees for professional assistance; but no medical man would accept fees from a medical student if the student was in poor circumstances, or was known to him personally, or was a pupil of the same medical school.—ED. L.

HIGH-POWER MICROSCOPY.

IN THE LANCET of July 11th, 1903, p. 116, we described the principal features of the microscope devised by Dr. Siedentopf in which "ultra-microscopical" particles of gold disseminated through ruby glass are rendered visible. The magnifying lenses are similar to those employed in ordinary high power work; the peculiar effects which have led to the instrument being called the ultra microscope are due to the illumination of the object by an intense beam of light directed at right angles to the axis of the optical system. No details of form or structure can, however, be made out in this way, the objects appearing merely as brilliant points seen against a dark background.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to *Advertisements* on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, P

Address in Medicine

ON

THE CIRCULATION VIEWED FROM THE PERIPHERY.

Delivered at the Seventy-fourth Annual Meeting of the British Medical Association on August 22nd, 1905,

By SIR JAMES BARR, M.D. GLASG., F.R.C.P. LOND., F.R.S. EDIN.,

SENIOR PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY; LECTURER ON CLINICAL MEDICINE, UNIVERSITY OF LIVERPOOL; MEDICAL VISITOR, TUEBROOK ASYLUM; VISITING PHYSICIAN, HAYDOCK LODGE ASYLUM; EXAMINER IN MEDICINE, UNIVERSITY OF GLASGOW.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—In the first place I must thank you, and through you the whole British Medical Association, for the high honour which has been conferred on me in my appointment to deliver this address. This is an honour and a privilege which happens to very few men, and that only once in a lifetime. I feel the dignity of the office and the obligations which it entails all the more deeply inasmuch as the invitation in the first place came from the members of the Association resident in this city. When the invitation was conveyed to me I rather hesitated to undertake a task which I felt I could only inadequately perform, but, on the other hand, I looked upon the request as a command, and it seemed to me that I could scarcely refuse to undertake a duty for which I had been selected by my Canadian brethren.

After accepting the task my difficulties began, and my first was in choosing a subject which would have a more or less general interest. I intuitively turned my attention to the circulation, the ramifications of which pervade the whole field, and as writers hitherto on this subject have almost invariably traced the circulation from the centre to the periphery it occurred to me that we might get a fresh view if we turned our attention in the opposite direction. There are numerous treatises on diseases of the heart and aorta, but until recent years a careful study of the peripheral circulation has been largely left to physiologists and pathologists. The experimental work of Cohnheim will ever remain a landmark in the pathology of the circulation, while to the school of Ludwig physiologists are no less indebted. To physiology medicine owes much and all great advances are being prosecuted along physiological lines. I have previously asserted that diseases of the heart most frequently arise from causes acting on the periphery, and hence there is here no room for specialism. The man who only studies the circulation with the aid of a stethoscope is a positive danger to society. I can, therefore, with an easy conscience and a sense of much satisfaction, devote some attention to that periphery.

The capillaries through which the interchange of nutritive pabulum and gases takes place between the blood and tissues play a most important rôle in the animal economy. Yet they have received very inadequate attention from clinicians. Perhaps it has been thought that their structure and position could be so briefly described that any circumlocution in their description was unnecessary. But however simple their structure, and however apparent their functions, they constitute a vast filter-bed for conveying nutritive material and oxygen to the tissues and for removing waste products therefrom. A careful study of how these changes take place and how the functions of these little tubes are carried on has always seemed to me a matter of as much importance as even the action of the heart itself. These little vessels are of extreme tenuity and delicacy, consisting of a single layer of endothelium, yet they are much stronger than most people imagine, and are capable of standing considerable internal pressure; they vary from about 0·5 to 1 millimetre in length, and from 7 to 13 micro-millimetres in diameter. They are to a certain extent elastic, or at least they have the capacity of adapting themselves to the amount of blood which is driven through them. Their importance has been aptly described by Leonard Hill, who says: "The blood is brought into intimate relation with the tissues by diffusing through the endothelial wall of the capillaries, and this wall is of great tenuity; thereby takes place that change of material which maintains the combustion of the body and the fire of life."

The capillary bed is a vast territory which pervades every tissue and organ of the body and so numerous are these little vessels that it would be difficult to stick the point of a needle in any vascular area without wounding one or more, but in neurotic individuals you may wound many such vessels without drawing blood. In very plethoric individuals and in cases of polycythæmia the capillaries of the body are fairly replete, but in ordinary mortals, especially in those of neurotic temperament, perhaps not a third of the capillaries are full at any one moment. Apply a sinapism to a very pallid skin and you may wonder where all the turgid capillaries have sprung from. From the fact that in normal circumstances a sufficient quantity of blood cannot get through the arterioles to keep the enormous capillary bed full the lateral pressure and the velocity in the capillaries are ever-varying quantities. When Leonard Hill stated that the pressure in the capillaries under certain conditions is often over 100 millimetres of mercury, I thought that there must be some error of observation as I was under the impression that such pressure would rupture these delicate little vessels, but I remembered the old advice: Do not think; try. I tried and found that Leonard Hill had rather understated the fact, as I found variations from about 50 to 2000 millimetres of water. I also found equally great variations in the velocity of the blood in the capillaries. In text-books on physiology it is put down from 0·2 to 0·75 millimetre per second but my observations have given records from about 0·5 millimetre to 25 millimetres per second. The capillary bed covers an enormous area; take, for example, the lungs where all the air vesicles are surrounded by a meshwork of capillaries and the surface of the air vesicles in the average individual has been calculated by Zuntz at 90 square metres. Numerous attempts have been made to estimate the capacity and sectional area of the capillaries but in my opinion these questions are still unsolved.

In a paper on tubal nephritis published in 1883 and in one on the pathology and treatment of dropsy in 1886 I dealt with the capillary circulation. I have long been in the habit of estimating the velocity by compressing the blood out of the capillaries in a given area and then watching the quickness or velocity of the return. This has served, and still serves, my purpose, but when I wish to record my observations I use a glass rod ten millimetres in diameter. With the flat end of this rod I compress the capillaries and then with a stop-watch recording fifths of a second I time the period of the return of the blood. If you divide the radius of this rod (five millimetres) by the time you get the velocity per second. For these observations you must select some spot where there is a network of capillaries which you can completely empty, such as those in the back of the hand or finger and you must also choose a spot where the return current flows from all parts of the circumference. This method is so simple and accurate that it is a matter of surprise to me that, so far as I know, it has never been thought of before.[1] When fluid is circulating in a capillary tube, the axial velocity is double the mean velocity. Now the erythrocytes travel in the axis but as they occupy at least four-fifths of the lumen of the vessel the mean must be fully 0·8 of the observed velocity. For estimating the pressure in the capillaries I use a modification of von Kries's apparatus. For applying the pressure I use three sizes of glass plates, measuring 20, 100, and 400 square millimetres, so a gramme pressure on each of these plates represents respectively 50, 10, and 2·5 millimetres of water. As before stated, I have recorded capillary pressures varying from 50 to 2000 millimetres of water and my velocity records have ranged from 0·5 millimetre to over 25 millimetres per second.

---

[1] Dr. George Oliver has drawn my attention to a capillary dynamometer devised by Dr. Alexander Haig for gauging the amount of uric acid in the circulation and estimating the blood pressure. Dr. Haig compresses the blood out of the capillaries under pressures varying from about five to 20 ounces and times the period of compression and of the capillary reflex. Dr. Haig says that his "instrument gives a constant definite area of pressure—a definite and measurable force, the pressure being applied for a definite and constant time, measured by a metronome beating half seconds, the length of time the blood and colour take to return being measured by the same instrument." Our methods are similar but our objects are different. At one time I thought of drawing up rules for estimating the arterial blood pressure by the capillary velocity but I soon found that the necessary corrections on account of the contraction or dilatation of the arterioles, the position and temperature of the part under examination, and perhaps the viscosity of the blood were so numerous as materially to lessen the clinical value of any such method.

[Sir James Barr here considered at some length the lateral pressure and velocity of the blood in the capillaries and the effects of gravity on the capillary pressure. He continued as follows:—]

I have shown that the capillary pressure in the foot, even when immobilised, is often less than that in the hand and much less than that in a grog-blossomed nose. This is entirely due to the wonderful mechanism of the vaso-motor system. Some people are very liable to cold feet in bed and such appendages to a lady seem to have led up to a divorce in the United States of America. In such cases the part may be fairly comfortable before going to bed, but once the horizontal posture is assumed the arterial pressure and capillary velocity fall, so that there is not a sufficient amount of fuel carried to the extremities to keep the large cooling surface warm. Here the defect is in the initial energy, and besides improving the general arterial pressure it would be advantageous to keep the feet much lower than the head and shoulders.

When the arterioles are dilated in any area, as at the commencement of an inflammation, the whole of the capillaries are opened up and engorged with blood, and with this increased mass the pressure is raised, but the velocity is also heightened owing to the arterial potential remaining high and the resistance in the enlarged capillaries being diminished. The resistance is inversely as the square of the cross sections, or the fourth power of the diameter, or directly as the square of the velocity. We have seen how hydrostatics affect the pressure in the capillaries, but the velocity is much more uniformly affected. It is usually sufficient to lower the hand 320 millimetres in order to double the velocity, and in the capillaries of the foot the velocity is usually extremely rapid. Velocity, $V = \sqrt{2gh}$; but in the capillaries we have further to take into account the sectional area, which has not yet been accurately computed either in whole or part.

So readily is the capillary velocity affected by the arterial pressure that, *ceteris paribus*, you can easily detect a difference between the velocity in the back of the hand and in the fingers: when a warm hand is hanging down the velocity in the finger is greater than in the back of the hand and if the relative position of these parts be altered the velocities are reversed. I purposely said a warm hand, because in a cold hand the capillary circulation in the fingers is often very languid. After removal of an Esmarch's tourniquet the capillary velocity in the flushed extremity is considerably augmented.

Any obstruction to the outflow from the capillaries diminishes the velocity in them. The hydrostatic effect of the blood in the veins would materially obstruct the capillary flow only for the provision of valves, and the muscular compression hastens on the blood and thus diminishes the statical condition. However, certain capillaries, such as those of the liver and kidneys, are exposed to considerable backward pressure when from any cause the venous pressure is raised. When the velocity in the capillaries is reduced to one millimetre or less per second the blood becomes surcharged with carbonic acid and the skin or organ supplied becomes of a dusky hue. This appearance immediately disappears if you increase the capillary velocity; for example, when the hand is blue and passively congested from cold, or the so-called local asphyxia, if you let it hang down you increase the velocity and you quickly see bright red spots intermingled with surrounding lividity, and soon the colour of the whole hand improves. In the cold livid dependent hand the colour of the fingers is better than that of the back of the hand. When you get cardiac failure, with or without any obstructive lung disease, you frequently see the upper part of the body and the hands quite dusky, while the legs and feet, which are at a lower level, may be pale. In one marked case of cardiac failure where the upper part of the body was livid I saw one foot and part of the leg in a state of local syncope and as pale as marble. These patients do not require a cylinder of oxygen with which they are frequently plied but the judicious application of a little common sense, such as the intravenous injection of small doses of adrenalin or some cardiac tonic. In cases of Raynaud's disease the local syncope is ascribed to vaso-motor spasm, but really the spasm, if it exists, is a very mild affair. In these cases the arterioles shut down because there is not sufficient blood pressure to keep them open. The arterial pressure is always low and the blood is deficient in lime salts and viscosity. In the cases of local asphyxia the arterioles are not closed, but the arterial potential is low, the velocity in the capillaries is defective, and the *vis viva* is not sufficient to drive on the blood stagnating in the veins. In cases of erythromelalgia the reverse happens; the velocity and pressure are both increased in the large engorged capillaries.

In many cases of pneumonia with low blood pressure the vaso-motor taps in the splanchnic area are all open and the aorta is drained before it terminates in the iliac arteries; the bulk of the blood is retained in the chest and abdomen and the quantity supplied to the lower limbs is diminished. Moreover, the extremities are often colder than the body and the arteries contracted. The lower level of the limbs increases the velocity in the capillaries and veins and consequently the capillaries of the foot and leg are often blanched and the veins comparatively empty when the upper part of the body appears congested and purple.

VISCOSITY OF THE BLOOD.

The viscosity varies greatly and is no doubt the great cause of resistance in the capillaries. Normally it is about five times that of distilled water, and my friend Dr. John H. Watson, who has recently been doing some valuable work on this subject in association with a physicist, Dr. A. Du Pré Denning, has found that in many diseases the viscosity is nine or ten times that of distilled water. The coefficient of viscosity in the tarry blood of Asiatic cholera is often so great that it will not pass through the capillaries. Dr. J. J. Graham Brown and others have found that a rise in temperature lessens the viscosity and hence a febrile temperature lessens the resistance and so diminishes the work of the heart, but it does not follow from this that a high temperature in fever is an advantage, as there are many more efficient ways of lessening the viscosity. Dr. Watson and Dr. Denning have devised a very convenient capillary viscosimeter which shows these variations in this physical property of the blood. They conclude that the chief resistance to the flow is due to the viscosity and occurs in the capillaries. It has long been a disputed point as to whether the resistance to the arterial flow, and consequently to the heart, is situated in the capillaries or arterioles.

Sir William H. Broadbent, I believe, even now throws the weight of his deservedly great name in favour of the resistance being in the capillaries; and in cases of vaso-motor paralysis no doubt such is the case, but in ordinary circumstances I agree with the majority that there is an earlier barrier to the outflow from the heart in the arterioles and small arteries which are governed by vaso-motor nerves. This can be readily proved by the fact that there is very little fall in the pressure-gradient from the large to the small arteries. The pressure in the radial and tibial at the same levels is as great as that in the brachial and femoral. When you come to the very small arteries and arterioles which are offering resistance to the flow there are a very great fall in the pressure and an increased velocity. The fall between the radial and digital artery may be as much as 50 millimetres of mercury, and there may be an even greater fall in the pressure-gradient between this and the capillaries. Now, if the capillaries formed the first line of resistance the fall in the pressure-gradient would be much more gradual and high arterial pressure would be associated with high capillary pressure, but we know the reverse to be the case.

It is extremely fortunate that there is this first line of defence created by the action of the vaso motor nerves in the small arteries and arterioles, because if this were wanting as at present constituted we should either have to go about on all fours or constantly run the risk of fatal syncope.

[Sir James Barr here quoted the opinions of several physiologists on various questions connected the viscosity of the blood. He continued as follows:—]

THE INTERCHANGE OF MATERIAL THROUGH THE CAPILLARY WALLS.

There are some physiologists who would raise the endothelial cells of the capillary walls to the high level of secreting structures; not that they have any evidence, either from analogy or otherwise, in support of such a contention, but simply because they think that the physical properties of diffusion, osmosis, and filtration cannot account for the phenomena. They hold that the capillary pressure is low and is more than counterbalanced by the endosmotic equivalent of the albumin and salts in the blood. When they recognise the enormous variation which takes place in the pressure and velocity of the blood in the capillaries they will have less difficulty in admitting the problem of filtration as applicable to the capillary circulation. The fall in the pressure-gradient in the capillaries must be fairly uniform from arteriole to venule, but as there is usually a considerable fall from the capillaries to the veins there must be a corresponding difference between the efferent and afferent capillaries and thus transudation and absorption in different parts of the same network can be readily explained. In the intestinal capillaries the larger and deeper vessels supply the secretory structures and the smaller and more superficial vessels are the absorbents.

The interchange of gases which are in solution readily takes place by the process of diffusion; and osmosis must play a very important part in transudation and absorption according as the osmotic equivalent is greater on one side or the other of the capillary membrane. In 1886, when dealing with the pathology of dropsy, I said: "Fluids pass very readily through organic membranes, such as the walls of the capillaries, by a process of osmosis, but albumins do not thus readily transude. Unlike the capillaries of the lungs and kidneys the systemic capillaries allow albumin to pass through their walls, so that it is found in all the intercellular fluids. Now, if it does not pass through by osmosis, we must suppose it to be filtered through under varying amounts of pressure. In filtering under pressure, as a rule, the greater the pressure the greater the amount of the filtrate, but the composition of the latter differs very materially from the nature of the compound fluid submitted to the pressure, as the different constituents pass through with varying degrees of ease, the water passing through much more readily than the albumin. Hence, although the total amount of albumin passed through may be increased according to the quantity of the filtrate, its percentage is diminished. Hence the greater and more rapid the production of dropsy—if there be no increase in absorption—the less the relative amount of albumin." Runeberg in 1882 expressed similar views when he maintained that the concentration of a colloid filtrate is greater at lower than at higher pressures.

THE ARTERIOLES AND CAPILLARIES OF THE SKIN.

The arterioles are well endowed with muscular fibre and vaso-motor nerves, chiefly of the constrictor type; frequently they are so contracted that the capillaries are almost empty, and in cases of local syncope quite empty, and the pressure and velocity fall to zero. When the vaso-motor nerves are paralysed from a central cause the capillaries are full, their pressure increased, and the velocity diminished. When paralysed from a local cause—such as a mustard poultice—the capillaries are engorged and the pressure and velocity increased. Witness also the effects following the application and removal of an Esmarch's tourniquet. These little vessels are reciprocal to those of the splanchnic area, and are largely concerned in regulating the temperature of the body and in maintaining the general arterial pressure.

The capillaries form an exceedingly close network in the corium and send loops up into the papillæ. The pressure and velocity vary enormously. After a liberal meal—especially one containing ingredients which dilate the arterioles, raise the diastolic arterial pressure, and thus provide an abundant supply of blood to, with increased pressure in, the capillaries—there is a free outpouring of lymph. In my opinion, a good deal of the work which has been done on the so-called digestion leucocytosis has been rendered worthless by the work of George Oliver on the tissue lymph circulation. These observations were made on blood obtained from a prick of the finger and this consists of a mixture of blood and lymph. The white cells are increased—the increase being in the lymphocytes—in proportion to the dilution with lymph and the red cells are proportionately diminished. If the lymph be compressed out of the tissues and then a drop of pure capillary blood be obtained there will be found in it an increase of red cells, and the white cells will be much less than in the mixed blood and scarcely any more than would be obtained by an ordinary puncture two or three hours later when the lymph had been reabsorbed. This so called digestion leucocytosis is therefore no evidence of any increase of white corpuscles in the circulating blood but merely that lymph has been pressed out from the vessels, and in this lymph there is a considerable number of leucocytes, probably obtained from the tissues rather than from the capillaries. There is, no doubt, a digestion leucocytosis but it is not what has been described.

[Sir James Barr here gave various details of the structure and physiology of the arterioles and capillaries of the splanchnic area and the kidneys, of the capillaries of the liver, and of the cerebral and coronary vessels. He continued as follows:]

THE PULMONARY CIRCULATION.

The pressure in the pulmonary artery is not more than one-third and the velocity of the blood about three-fourths of those respective conditions in the aorta; but, unlike the vena cava, the pressure in the pulmonic veins is always positive, so that the blood always enters the left side of the heart under pressure, while it is usually sucked into the right side. There is a gradual fall of the pressure-gradient from the right ventricle to the left auricle and there does not seem to be much resistance to the circulation either in the arterioles or capillaries. Bradford and Dean and François Franck have shown by a series of very elaborate experiments that the pulmonic vessels are innervated; but while such innervation may be sufficient to maintain slight tone in the vessels some experiments with adrenalin would show that it cannot constrict the vessels so as to effectively increase the resistance.

Respiration renders great assistance in carrying on the circulation to the right side of the heart and to a less extent to the left. That the assistance extends to the whole circulation is shown by the fall in the arterial pressure which occurs at the beginning of inspiration. In the so-called pulsus paradoxus (there is no paradox but merely an exaggeration of a perfectly normal phenomenon) and in Müller's experiment of expanding the chest with the glottis shut the pulse may disappear at the wrist. This is due to the sudden emptying of the veins to fill up the vacuum in the chest and with this removal of the obstruction to the capillary flow there is a simultaneous depletion of the arteries. It is not due, as has been supposed by Kussmaul, to any kinking of the large vessels, or to any sucking back of the blood into the aorta, as has been imagined by those who seem to have forgotten that the pressure in the aorta is always high and cannot be affected by a negative pressure in the thorax. It is due to a certain fall in pressure affecting the veins, capillaries, and arteries, and it is most marked in cases of low arterial pressure. When the arterioles are much contracted and the arterial tension high, as in cases of Bright's disease, it does not occur. The lungs form a blood reservoir for the left side of the heart and during this expansion the reservoir is increased and has to be filled up before the left side of the heart is sufficiently well supplied with blood to enable it to throw the proper quantities into the aorta at each systole; the arteries are therefore emptied at their distal end and not filled at their proximal end and so the pulse disappears until an equilibrium is restored.

I recently had a very good example of this in a case of bradycardia under my care where the frequency of the pulse varied from 12 to 24 beats in the minute. When Dr. John Hay and my house physician, Dr. Jones, were taking cardiographic and sphygmographic tracings I found that when the patient took a long deep breath and then held his chest expanded as long as possible the following events occurred During the deep inspiration there were two beats of the heart and two pulses at the wrist, then the pulse disappeared in the carotid, brachial, radial, and femoral arteries, and remained absent for several beats. At the same time the impulse of the heart disappeared and the clear loud first sound and systolic murmur were replaced by a low, dull-toned, obscure sound, and the second sound was not audible. After four or five faint systoles, which I attributed to the right ventricle, the clear first sound and systolic murmur and the double second sound reappeared and were associated with a return of the pulse in all the arteries. Here undoubtedly the blood was stored up in the lung reservoir and the proper systoles of the left ventricle and the pulse in the arteries did not reappear until the reservoir overflowed. He had several attacks of semi-consciousness and one slight epileptic seizure during the periods of suspended breathing with the chest expanded. These attacks always occurred after the pulse had ceased for about 20 seconds

In 19 4 Dr George Oliver gave a great stimulus to the study of the peripheral circulation by the publication of his admirable work on the tissue-lymph circulation. He showed ranged from 0·5 millimetre to over 25 millimetres per second.

[Sir James Barr here considered at some length the lateral pressure and velocity of the blood in the capillaries and the effects of gravity on the capillary pressure. He continued as follows:—]

I have shown that the capillary pressure in the foot, even when immobilised, is often less than that in the hand and much less than that in a grog-blossomed nose. This is entirely due to the wonderful mechanism of the vaso-motor system. Some people are very liable to cold feet in bed and such appendages to a lady seem to have led up to a divorce in the United States of America. In such cases the part may be fairly comfortable before going to bed, but once the horizontal posture is assumed the arterial pressure and capillary velocity fall, so that there is not a sufficient amount of fuel carried to the extremities to keep the large cooling surface warm. Here the defect is in the initial energy, and besides improving the general arterial pressure it would be advantageous to keep the feet much lower than the head and shoulders.

When the arterioles are dilated in any area, as at the commencement of an inflammation, the whole of the capillaries are opened up and engorged with blood, and with this increased mass the pressure is raised, but the velocity is also heightened owing to the arterial potential remaining high and the resistance in the enlarged capillaries being diminished. The resistance is inversely as the square of the cross sections, or the fourth power of the diameter, or directly as the square of the velocity. We have seen how hydrostatics affect the pressure in the capillaries, but the velocity is much more uniformly affected. It is usually sufficient to lower the hand 320 millimetres in order to double the velocity, and in the capillaries of the foot the velocity is usually extremely rapid. Velocity, $V = \sqrt{2gh}$; but in the capillaries we have further to take into account the sectional area, which has not yet been accurately computed either in whole or part.

So readily is the capillary velocity affected by the arterial pressure that, *ceteris paribus*, you can easily detect a difference between the velocity in the back of the hand and in the fingers: when a warm hand is hanging down the velocity in the finger is greater than in the back of the hand and if the relative position of these parts be altered the velocities are reversed. I purposely said a warm hand, because in a cold hand the capillary circulation in the fingers is often very languid. After removal of an Esmarch's tourniquet the capillary velocity in the flushed extremity is considerably augmented.

Any obstruction to the outflow from the capillaries diminishes the velocity in them. The hydrostatic effect of the blood in the veins would materially obstruct the capillary flow only for the provision of valves, and the muscular compression hastens on the blood and thus diminishes the statical condition. However, certain capillaries, such as those of the liver and kidneys, are exposed to considerable backward pressure when from any cause the venous pressure is raised. When the velocity in the capillaries is reduced to one millimetre or less per second the blood becomes surcharged with carbonic acid and the skin or organ supplied becomes of a dusky hue. This appearance immediately disappears if you increase the capillary velocity; for example, when the hand is blue and passively congested from cold, or the so-called local asphyxia, if you let it hang down you increase the velocity and you quickly see bright red spots intermingled with surrounding lividity, and soon the colour of the whole hand improves. In the cold livid dependent hand the colour of the fingers is better than that of the back of the hand. When you get cardiac failure, with or without any obstructive lung disease, you frequently see the upper part of the body and the hands quite dusky, while the legs and feet, which are at a lower level, may be pale. In one marked case of cardiac failure where the upper part of the body was livid I saw one foot and part of the leg in a state of local syncope and as pale as marble. These patients do not require a cylinder of oxygen with which they are frequently plied but the judicious application of a little common sense, such as the intravenous injection of small doses of adrenalin or some cardiac tonic. In cases of Raynaud's disease the local syncope is ascribed to vaso-motor spasm, but really the spasm, if it exists, is a very mild affair. In these cases the arterioles shut down because there is not sufficient blood pressure to keep them open. The arterial pressure is always low and the blood is deficient in lime salts and viscosity. In the cases of local asphyxia the arterioles are not closed, but the arterial potential is low, the velocity in the capillaries is defective, and the *vis viva* is not sufficient to drive on the blood stagnating in the veins. In cases of erythromelalgia the reverse happens; the velocity and pressure are both increased in the large engorged capillaries.

In many cases of pneumonia with low blood pressure the vaso-motor taps in the splanchnic area are all open and the aorta is drained before it terminates in the iliac arteries; the bulk of the blood is retained in the chest and abdomen and the quantity supplied to the lower limbs is diminished. Moreover, the extremities are often colder than the body and the arteries contracted. The lower level of the limbs increases the velocity in the capillaries and veins and consequently the capillaries of the foot and leg are often blanched and the veins comparatively empty when the upper part of the body appears congested and purple.

VISCOSITY OF THE BLOOD.

The viscosity varies greatly and is no doubt the great cause of resistance in the capillaries. Normally it is about five times that of distilled water, and my friend Dr. John H. Watson, who has recently been doing some valuable work on this subject in association with a physicist, Dr. A. Du Pré Denning, has found that in many diseases the viscosity is nine or ten times that of distilled water. The coefficient of viscosity in the tarry blood of Asiatic cholera is often so great that it will not pass through the capillaries. Dr. J. J. Graham Brown and others have found that a rise in temperature lessens the viscosity and hence a febrile temperature lessens the resistance and so diminishes the work of the heart, but it does not follow from this that a high temperature in fever is an advantage, as there are many more efficient ways of lessening the viscosity. Dr. Watson and Dr. Denning have devised a very convenient capillary viscosimeter which shows these variations in this physical property of the blood. They conclude that the chief resistance to the flow is due to the viscosity and occurs in the capillaries. It has long been a disputed point as to whether the resistance to the arterial flow, and consequently to the heart, is situated in the capillaries or arterioles.

Sir William H. Broadbent, I believe, even now throws the weight of his deservedly great name in favour of the resistance being in the capillaries; and in cases of vaso-motor paralysis no doubt such is the case, but in ordinary circumstances I agree with the majority that there is an earlier barrier to the outflow from the heart in the arterioles and small arteries which are governed by vaso-motor nerves. This can be readily proved by the fact that there is very little fall in the pressure-gradient from the large to the small arteries. The pressure in the radial and tibial at the same levels is as great as that in the brachial and femoral. When you come to the very small arteries and arterioles which are offering resistance to the flow there are a very great fall in the pressure and an increased velocity. The fall between the radial and digital artery may be as much as 50 millimetres of mercury, and there may be an even greater fall in the pressure-gradient between this and the capillaries. Now, if the capillaries formed the first line of resistance the fall in the pressure-gradient would be much more gradual and high arterial pressure would be associated with high capillary pressure, but we know the reverse to be the case.

It is extremely fortunate that there is this first line of defence created by the action of the vaso motor nerves in the small arteries and arterioles, because if this were wanting as at present constituted we should either have to go about on all fours or constantly run the risk of fatal syncope.

[Sir James Barr here quoted the opinions of several physiologists on various questions connected the viscosity of the blood. He continued as follows:—]

THE INTERCHANGE OF MATERIAL THROUGH THE CAPILLARY WALLS.

There are some physiologists who would raise the endothelial cells of the capillary walls to the high level of secreting structures; not that they have any evidence, either from analogy or otherwise, in support of such a contention, but simply because they think that the physical properties of diffusion, osmosis, and filtration cannot account for the phenomena. They hold that the capillary pressure is low and is more than counterbalanced by the endosmotic equivalent of the albumin and salts in the blood. When they recognise the enormous variation which takes place in the pressure and velocity of the blood in the capillaries they will have less difficulty in admitting the problem of filtration as applicable to the capillary circulation. The fall in the pressure-gradient in the capillaries must be fairly uniform from arteriole to venule, but as there is usually a considerable fall from the capillaries to the veins there must be a corresponding difference between the efferent and afferent capillaries and thus transudation and absorption in different parts of the same network can be readily explained. In the intestinal capillaries the larger and deeper vessels supply the secretory structures and the smaller and more superficial vessels are the absorbents.

The interchange of gases which are in solution readily takes place by the process of diffusion; and osmosis must play a very important part in transudation and absorption according as the osmotic equivalent is greater on one side or the other of the capillary membrane. In 1886, when dealing with the pathology of dropsy, I said: "Fluids pass very readily through organic membranes, such as the walls of the capillaries, by a process of osmosis, but albumins do not thus readily transude. Unlike the capillaries of the lungs and kidneys the systemic capillaries allow albumin to pass through their walls, so that it is found in all the intercellular fluids. Now, if it does not pass through by osmosis, we must suppose it to be filtered through under varying amounts of pressure. In filtering under pressure, as a rule, the greater the pressure the greater the amount of the filtrate, but the composition of the latter differs very materially from the nature of the compound fluid submitted to the pressure, as the different constituents pass through with varying degrees of ease, the water passing through much more readily than the albumin. Hence, although the total amount of albumin passed through may be increased according to the quantity of the filtrate, its percentage is diminished. Hence the greater and more rapid the production of dropsy—if there be no increase in absorption—the less the relative amount of albumin." Runeberg in 1882 expressed similar views when he maintained that the concentration of a colloid filtrate is greater at lower than at higher pressures.

THE ARTERIOLES AND CAPILLARIES OF THE SKIN.

The arterioles are well endowed with muscular fibre and vaso-motor nerves, chiefly of the constrictor type; frequently they are so contracted that the capillaries are almost empty, and in cases of local syncope quite empty, and the pressure and velocity fall to zero. When the vaso-motor nerves are paralysed from a central cause the capillaries are full, their pressure increased, and the velocity diminished. When paralysed from a local cause—such as a mustard poultice—the capillaries are engorged and the pressure and velocity increased. Witness also the effects following the application and removal of an Esmarch's tourniquet. These little vessels are reciprocal to those of the splanchnic area, and are largely concerned in regulating the temperature of the body and in maintaining the general arterial pressure.

The capillaries form an exceedingly close network in the corium and send loops up into the papillæ. The pressure and velocity vary enormously. After a liberal meal—especially one containing ingredients which dilate the arterioles, raise the diastolic arterial pressure, and thus provide an abundant supply of blood to, with increased pressure in, the capillaries—there is a free outpouring of lymph. In my opinion, a good deal of the work which has been done on the so-called digestion leucocytosis has been rendered worthless by the work of George Oliver on the tissue lymph circulation. These observations were made on blood obtained from a prick of the finger and this consists of a mixture of blood and lymph. The white cells are increased—the increase being in the lymphocytes—in proportion to the dilution with lymph and the red cells are proportionately diminished. If the lymph be compressed out of the tissues and then a drop of pure capillary blood be obtained there will be found in it an increase of red cells, and the white cells will be much less than in the mixed blood and scarcely any more than would be obtained by an ordinary puncture two or three hours later when the lymph had been reabsorbed. This so-called digestion leucocytosis is therefore no evidence of any increase of white corpuscles in the circulating blood but merely that lymph has been pressed out from the vessels, and in this lymph there is a considerable number of leucocytes probably obtained from the tissues rather than from the capillaries. There is, no doubt, a digestion leucocytosis but it is not what has been described.

[Sir James Barr here gave various details of the structure and physiology of the arterioles and capillaries of the splanchnic area and the kidneys, of the capillaries of the liver, and of the cerebral and coronary vessels. He continued as follows:]

THE PULMONARY CIRCULATION.

The pressure in the pulmonary artery is not more than one-third and the velocity of the blood about three-fourths of those respective conditions in the aorta; but, unlike the vena cava, the pressure in the pulmonic veins is always positive, so that the blood always enters the left side of the heart under pressure, while it is usually sucked into the right side. There is a gradual fall of the pressure-gradient from the right ventricle to the left auricle and there does not seem to be much resistance to the circulation either in the arterioles or capillaries. Bradford and Dean and François Franck have shown by a series of very elaborate experiments that the pulmonic vessels are innervated; but while such innervation may be sufficient to maintain slight tone in the vessels some experiments with adrenalin would show that it cannot constrict the vessels so as to effectively increase the resistance.

Respiration renders great assistance in carrying on the circulation to the right side of the heart and to a less extent to the left. That the assistance extends to the whole circulation is shown by the fall in the arterial pressure which occurs at the beginning of inspiration. In the so-called pulsus paradoxus (there is no paradox but merely an exaggeration of a perfectly normal phenomenon) and in Müller's experiment of expanding the chest with the glottis shut the pulse may disappear at the wrist. This is due to the sudden emptying of the veins to fill up the vacuum in the chest and with this removal of the obstruction to the capillary flow there is a simultaneous depletion of the arteries. It is not due, as has been supposed by Kussmaul, to any kinking of the large vessels, or to any sucking back of the blood into the aorta, as has been imagined by those who seem to have forgotten that the pressure in the aorta is always high and cannot be affected by a negative pressure in the thorax. It is due to a certain fall in pressure affecting the veins, capillaries, and arteries, and it is most marked in cases of low arterial pressure. When the arterioles are much contracted and the arterial tension high, as in cases of Bright's disease, it does not occur. The lungs form a blood reservoir for the left side of the heart and during this expansion the reservoir is increased and has to be filled up before the left side of the heart is sufficiently well supplied with blood to enable it to throw the proper quantities into the aorta at each systole; the arteries are therefore emptied at their distal end and not filled at their proximal end and so the pulse disappears until an equilibrium is restored.

I recently had a very good example of this in a case of bradycardia under my care where the frequency of the pulse varied from 12 to 24 beats in the minute. When Dr. John Hay and my house physician, Dr. Jones, were taking cardiographic and sphygmographic tracings I found that when the patient took a long deep breath and then held his chest expanded as long as possible the following events occurred During the deep inspiration there were two beats of the heart and two pulses at the wrist, then the pulse disappeared in the carotid, brachial, radial, and femoral arteries, and remained absent for several beats. At the same time the impulse of the heart disappeared and the clear loud first sound and systolic murmur were replaced by a low, dull-toned, obscure sound, and the second sound was not audible. After four or five faint systoles, which I attributed to the right ventricle, the clear first sound and systolic murmur and the double second sound reappeared and were associated with a return of the pulse in all the arteries. Here undoubtedly the blood was stored up in the lung reservoir and the proper systoles of the left ventricle and the pulse in the arteries did not reappear until the reservoir overflowed. He had several attacks of semi-consciousness and one slight epileptic seizure during the periods of suspended breathing with the chest expanded. These attacks always occurred after the pulse had ceased for about 20 seconds

In 19 5 Dr George Oliver gave a great stimulus to the study of the peripheral circulation by the publication of his admirable work on the tissue-lymph circulation. He showed that during the first hour of digestion there was a rise in the blood pressure—arterial, capillary, and venous—with a flow of lymph into the tissues; during this wave there might be a difference of from 10 to 20 per cent. in the number of erythrocytes and in the hæmoglobin between the mixture of blood and lymph obtained by a simple prick of the finger and that of the pure capillary blood obtained from the same prick after the lymph had been compressed out of the finger. He also showed that the same extracapillary lymph flow occurred in the muscles and prevented any further rise in the arterial pressure from tension exercises. His observations led him to the following conclusions: "1. That the food constituents themselves (proteids, fats, and carbohydrates) do not possess the power of starting the mechanism by which lymph is dispensed to the tissues through the body. 2. That Nature, however, associates with our foodstuffs small quantities of very active substances which, bring into play that mechanism, though these substances themselves are practically devoid of food value, and that man frequently increases this natural lymph by the use of salt and beverages containing bodies which also incite the flow of lymph. Such bodies as uric acid, creatin, creatinin, xanthin, glycogen, and sodium chloride perform an important function in nutrition, for during digestion they act as distributors of lymph to all the tissues—an office which the nutrient constituents themselves (proteids, fats, and carbohydrates) are incapable of discharging." Dr. Oliver associated the action of these lymphagogues with a rise in capillary blood pressure, but in 1891 Heidenhain had ascribed the action of such agents to a specific excitation of the secretory activities of the endothelial cells. We have before referred to the careful experimental work of Starling in 1893, by which he refuted the conclusion of Heidenhain and re-established the doctrine of filtration under pressure.

When a person is standing the venous pressure in the foot is raised, but so also is the arterial. Supposing in the circumstances you have a venous pressure in the foot of 100 millimetres of mercury obstructing the capillary flow and an arterial pressure of 300 millimetres of mercury, you have a difference of 200 millimetres of mercury driving the blood through the capillaries with great velocity and very little lateral pressure. If, then, the subject assume the horizontal posture, and raise the foot till the venous pressure be *nil*, there will be a corresponding fall in the arteries of 100 millimetres of mercury, but there will still remain the same difference between the arteries and veins of 200 millimetres. The following physical experiment readily explains this question of pressure and velocity. If you construct a U-shaped tube out of india-rubber tubing, having both the limbs very wide, and a short connexion made of very fine tubing, then make a small hole in each of the three pieces and connect one of the limbs with a water-tap, you will then find that the water comes out in a forcible jet from the hole in the proximal limb or artery, with less force from the hole in the distal limb or vein, but from the hole in the capillary there is no escape; the energy in it is all converted into velocity. If you compress the vein, then you raise the lateral pressure in the capillary and thus cause an escape. In the healthy individual the arteries of the lower limbs are firmly contracted, and although the pressure is high the mass of blood on which it acts is relatively small and consequently the energy in the capillaries is largely converted into velocity. In proportion as you obstruct the outflow from the capillaries you increase the lateral pressure and diminish the velocity in them and consequently increase the transudation. In cases of vaso-motor paresis and in cases of cardiac failure the mass of blood in the capillaries of the dependent limb is augmented, the pressure is increased, and the velocity is diminished; consequently you get œdema.

The Veins.

The veins are smooth, capacious vessels, which practically offer no resistance to the circulating blood. They contain a certain amount of muscular fibre, and are supplied with some vaso-motor nerves, which maintain their tone and to some extent regulate their capacity. The great strength of the veins depends on the strong fibrous external coat. They are slightly elastic and attain their *maximum* distension at a low internal pressure; in this respect they differ essentially from their corresponding arteries. The veins have very flaccid walls and consequently readily adjust their cubic space to the amount of blood in transit. It has been shown by MacWilliam and by Leonard Hill that veins contract on mechanical stimulation or by cold and dilate by heat. The coefficient of elasticity increases with the internal pressure. The lateral pressure in the systemic veins depends on three factors—namely: (1) the obstruction to the inflow to the chest; (2) the hydrostatic effect of the column of blood; and (3) the potential energy transmitted through the capillaries. In the portal vein the pressure is always positive and in this respect it resembles an artery.

Velocity in the Veins.

The blood in the veins is one of the very few things which run more quickly up the hill than they do down it. The velocity depends on the *vis a tergo* and varies enormously; in the veins of the arm it is frequently five times greater when the arm is hanging than when it is held horizontally at the level of the shoulder. The velocity is calculated by emptying a long piece of vein between two valves and then timing with a stop-watch the period it takes the blood to fill the empty vein. I have seen 23 centimetres of a vein in a dependent arm filled in 0·2 of a second, or a velocity of 115 centimetres in the second, a velocity as great as often occurs in the aorta. As in this case viscosity and friction can be left out of account, the only resistance to the flow was the retarding influence of gravity which can be easily calculated. The resistance would just equal the accelerating influence of gravity on a body falling *in vacuo* through a height of 23 centimetres, and from the formula $V = \sqrt{2gh}$, we know that this would equal a terminal velocity of 2100 millimetres per second. This is equivalent to a pressure of 230 millimetres of blood and equals the resistance, but in order to attain a velocity of 1150 millimetres in the second over and above the resistance of gravity, we must have a pressure which would give a velocity of 3250 millimetres in the second, which would be obtained by the pressure of a column of blood of 530 millimetres in height. The pressure-gradient in these 23 centimetres of vein would, therefore, be a fall from 530 to 300 millimetres of blood, or from 40 to 23 millimetres of mercury. This calculation was borne out by observation with a hæmometer. In these calculation, mercury is reckoned as 13 times heavier than blood. Where the resistance is *nil* a pressure gradient of five millimetres of mercury in a vein will give you a velocity of 1120 millimetres in the second. These observations show how kinetic and potential energy in every part of the circulation is constantly varying.

The Arteries.

As the blood leaves the heart its energy is largely kinetic and therefore there must be very little lateral pressure at the commencement of the aorta during ventricular systole, but if the aorta be healthy a large portion of this energy is rapidly stored up in the elastic walls as potential which is paid out during the diastolic period and then the blood is compressed with a force nearly equal to that which it exercised, and this applies to all portions, including the commencement. The velocities of the blood in the aorta and pulmonary artery vary considerably in different individuals and in the same individual under different conditions. The velocity is directly as the cardiac energy and inversely as the resistance to the outflow and the sectional area. The force of the right ventricle is not a third of that of the left but the resistance is also not a third of that in the systemic vessels; the sectional area is only slightly greater, therefore the velocity in the pulmonary artery is nearly equal to that in the aorta.

In my opinion physiologists place too low an estimate on the velocity of the blood in the aorta, though no doubt their conclusions are based on many careful experiments, but experiments very difficult to carry out and very liable to great fallacies. Chauveau found that the velocity in the carotid artery of the horse reached 520 millimetres per second during systole, while at the time of the dicrotic wave the velocity sank to 220 millimetres per second and in diastole to 150 millimetres per second. In the human aorta the mean velocity has been set down as 320 millimetres to the second, while Professor Sherrington is a little more liberal with 500 millimetres. Now, a fall in the pressure-gradient in the aorta from 100 to 80 millimetres of mercury gives you a theoretical velocity of 525 millimetres per second. A clear comprehension of these questions of velocity and pressure in the aorta is essential for any true knowledge as to how stress and strain produce atheromatous and sclerotic changes in the vessels. There is no more important subject in the whole domain of medicine, as, after the age of 50, arterio-sclerosis, directly or indirectly, kills more people than any other disease.

We have seen that a pressure-gradient of five millimetres of mercury in a vein without any resistance would give a velocity of 1120 millimetres in the second, but in an artery, in order to get a velocity of 1120 millimetres you require a fall in the pressure-gradient from 150 to 100 millimetres of mercury. With a pressure of 150 millimetres and a resistance of 120 millimetres of mercury to the outflow you get a velocity of 640 millimetres in the second. With this velocity there is no excessive longitudinal strain on the vessel and provided the lateral pressure in the aorta does not exceed 150 millimetres of mercury the elasticity of the vessel may be preserved till old age. This ideal is not often realised.

When you get a continuous lateral pressure of 200 millimetres of mercury or more there is no period of repose for the vessels but merely periods of greater or less distension; there is interference with the circulation in the nutritive vessels, the vasa vasorum; you get irritative and proliferative changes in the subendothelial layer of the intima, atheromatous and perhaps calcareous degeneration follow, and the elasticity of the aorta becomes impaired. Oskar Klotz says that all the aortas examined by him coming from persons over 25 years of age showed more or less calcareous change in the aortic wall. In proportion to the loss of the elasticity the energy of the heart is not stored up and with the loss in the conservation of energy the heart has got more work to do in order to carry on the circulation and a great disparity arises between the systolic and diastolic pressures. In these cases the immediate resistance to the outflow from the heart is not increased but the total work is greater, the diastolic pressure in the heart rises, and the ventricle dilates and hypertrophies. The output is increased, the velocity is increased, and longitudinal straining—especially along the greater curvature of the arch of the aorta—takes place. When failure begins to set in you may find the force of this big powerful organ which shakes the whole chest only poorly represented at the periphery. In these cases the storage is defective, the pressure and the velocity are more or less intermittent, and there is an enormous waste of energy. In cases of very free aortic regurgitation the difference in the pressure-gradient and consequently in the velocity is often very great, the cardiac hypertrophy becomes extreme, and subsequent failure rapidly takes place.

This question of storage forms an important element in prognosis and for this reason aortic regurgitation occurring early in life from a rheumatic lesion when the aorta is fairly healthy is, *ceteris paribus*, very much less serious than a similar lesion arising secondary to degeneration of the aorta. If there be any elasticity left in the aorta and principal branches there is an advantage in aortic regurgitation in maintaining a relatively high diastolic pressure, because you thus make circulation more uniform and you do not necessarily raise the systolic pressure or increase the work of the heart. For these reasons well-regulated doses of digitalis and squills often do an enormous amount of good in this disease, notwithstanding the fact that many well-recognised authorities have entirely condemned the use of digitalis in aortic regurgitation, possibly because they did not know how to use it.

While a combination of these drugs increases the peripheral resistance—which is an advantage if moderate in amount—they lessen the size of the ventricle, increase the length and completeness of contraction, diminish the residual blood, and thus lower the diastolic pressure in the ventricles. In the present day it is a very common, and occasionally beneficial, practice to combine cardiac tonics with vaso-motor relaxants, such as digitalis and nitro-glycerine, but before combining opposing forces I think it is always well to have a clear indication in your mind as to the objects which you wish to accomplish, and the results which are likely to be attained. The circulation of the blood is one of the most perfect pieces of mechanism in the universe, and no amateur should be trusted to keep it in repair, yet American and English people pour tons of baneful drugs down their throats every year on the recommendation of advertising quacks, who care nothing for the lives and health of the community, and care for nothing but their money.

Arterial Blood Pressure.

During recent years an enormous amount of literature has been devoted to what has been euphemistically described as blood pressure. With one of the numerous blood-pressure instruments which are on the market it might seem a very simple matter to make an observation, but it must be remembered that it is not the instrument, but the man behind the instrument, who makes or mars the observation. The arterial pressure at the level of the heart depends on the force of the cardiac systole and the resistance to the outflow through the arterioles and capillaries. With a healthy heart or self-regulating pump the greater the resistance the greater the force of the cardiac contraction and consequently the higher the lateral pressure on the walls of the arteries. If the resistance be too great we may get cardiac failure and then the pressure falls. A long-continued great resistance increases the work of the heart, and work leads to hypertrophy which maintains the pressure at a high level. In a healthy aorta the coefficient of elasticity increases with the internal pressure, but long-continued strain impairs the elasticity and leads to degenerative changes in the intima. Roy considered that the maximum distensibility of an artery occurred under pressures corresponding more or less exactly to their normal blood pressure, but since then MacWilliam has shown that this is an error due, no doubt, to Roy unwittingly using arteries in a state of post-mortem contraction. MacWilliam has shown that the behaviour of an artery under varying degrees of internal pressure depends on the state of contraction or relaxation of the vessel and on the relative amount of elastic and muscular tissue.

When a person is in the horizontal posture there is still the same pressure-gradient between the systolic and diastolic pressures and in all the arteries of the limbs these respective pressures are about similar levels. The postural variations in pressure have been thoroughly investigated by Leonard Hill and placed on a true scientific basis. These variations are of importance not only from a physiological but also from a pathological standpoint. In arterio-sclerotic changes the arteries of the lower limbs are most involved, notwithstanding their muscular development and good vaso-motor nerve-supply. These arteries take part in raising the general arterial pressure and are also subjected to additional internal strain from the statical pressure of the blood; hence both the middle and internal coats are involved in the sclerotic changes.

In arterio-sclerosis the middle coat is chiefly thickened in the muscular arteries and arterioles which take part in raising the general arterial pressure, such as those of the splanchnic area, the skin, and muscles; while in those arteries which are not very muscular and are subjected to internal strain from both high systolic and diastolic pressures the intima is principally involved. Hence atheroma and calcareous degeneration are very common in the aorta and in the commencement of its branches, and in the coronary and cerebral arteries. The carotid arteries seem to occupy an intermediate position; they are muscular and very contractile, and are not specially liable to sclerotic changes either in the intima or the media.

In my writings on arterio sclerosis I entered very fully into the numerous causes which give rise to this disease, and the pathological aspect of the subject has been well investigated by Councilman, Cowan, Russell, Welch, and a host of others. A life of indolence and luxury is more deleterious to the circulation than the work of a navvy. I must not be supposed as recommending either course of life, but a happy mean with a strong leaning towards hard work.

The Heart.

No survey of the circulation would be complete without a reference to the self-regulating pump. The heart is composed of two physiologically distinct organs—the right and left heart. Each has got its own varying amount of work to perform and it in normal circumstances, performs it without any assistance from the other, but in cases of stress or difficulty they mutually assist one another. They act together, and are set to the same time, but this does not prevent one side from beginning or ending contraction before the other, and so much so is this the case—and they are at least to this extent independent—that doubling of both sounds of the heart is one of the most common of cardiac phenomena. In a healthy heart both sounds are usually doubled every deep respiration.

Ladies and gentlemen, I have said enough to show you the necessity of a well-balanced circulation for the maintenance of life and health. It is only with healthy blood-vessels that anyone can hope to retain his mental and bodily vigour and expect to attain a green old age. Like the circulation, let us run with patience the race which is set before us. "Life every man holds dear, but the brave man holds honour more precious dear than life."

Address in Surgery

ON

THE TECHNIQUE OF OPERATIONS ON THE CENTRAL NERVOUS SYSTEM.

Delivered at the Seventy-fourth Annual Meeting of the British Medical Association on August 22nd, 1906,

BY SIR VICTOR HORSLEY, F.R.C.S. ENG., F.R.S.,

LATE CHAIRMAN OF THE REPRESENTATIVE MEETING OF THE BRITISH MEDICAL ASSOCIATION, SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON, AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, LONDON, W.C.

[Sir Victor Horsley commenced his address by defining the limits within which he intended to speak. 20 years ago, he said, he had shown at a meeting of the Association the first three patients upon whom he had operated at the National Hospital for the Paralysed and Epileptic for intracranial disease. During the interval further experimental research on animals and clinical observations upon human beings had confirmed the soundness of the treatment that he then laid down; and in his address he proposed to analyse his cases at the National Hospital and to show that an accumulation of facts now afforded a ready answer to many important questions of diagnosis and prognosis. He continued:—]

THE RESPONSIBILITY OF THE SURGEON.

I must first briefly allude to the responsibility of the surgeon in the treatment of diseases of the central nervous system. As in all special branches of medicine and surgery which are in a process of evolution it is not easy to assign credit or blame when the course of treatment pursued is respectively successful or unsuccessful; but so long as our powers of diagnosis remain as imperfect as they are so long will the vulgar error of regarding surgical treatment as a *dernier ressort* be committed. This question—namely, When should medicinal treatment be given up and operative treatment substituted?—has been raised again and again and hotly discussed in connexion with many diseases, notably appendicitis. In 1890, hoping to secure a more logical and definite pronouncement on this fundamental point at the International Medical Congress, I proposed that in cases of Jacksonian epilepsy and other syndromata which suggested the existence of gross organic disease of the brain a definite probationary period of medicinal treatment should be agreed upon and that in an elementary case where no urgent symptoms like optic neuritis existed surgical treatment should be employed after thorough drug medication had been energetically applied for about six or eight weeks and cure had not appreciably resulted. No conclusion, however, was arrived at. Again, in 1893 I was unable to get an expression of opinion on this point, although Dr. Allan Starr in his well-known work on "Brain Surgery," has also formulated the conclusion that the surgeon should be invited to consultation in the case after about three months' medical treatment had been unsuccessful. Although such a course is in general the practice at the Queen Square Hospital, this view of the situation unfortunately has not yet been discussed in the profession. Even in the present year I have been asked to operate on a patient with a lateral tumour of the cerebellum who had been known to have optic neuritis for nine years, and last year I did operate on such a patient who had been known to have optic neuritis for 13 years. It is, of course, perfectly ridiculous to include such cases in surgical statistics purporting to be a scientific study of this subject, and I only mention them to show what extraordinary ideas still prevail of our responsibility towards the victims of diseased conditions when such happen to constitute what are termed new subjects in medicine and surgery.

Assuming now that in a given case surgical treatment is considered advisable, the question immediately arises for what precise purpose is it to be employed, for all treatment, medical or surgical, is either palliative or curative. These two aspects of the matter require separate consideration.

PALLIATIVE SURGICAL PROCEDURES.

It is a prominent characteristic of intracranial disease that (1) it is liable to produce optic neuritis, which customarily ends in total blindness; and (2) it may concomitantly cause severe headache and vomiting, all of which symptoms are dependent upon pressure and can be completely palliated or wholly removed by making a sufficiently free opening in the skull and dura mater.

Optic neuritis is a condition which, owing to its causing blindness, is of such vital importance to the interest of the patient, and so to the community, that it merits full attention. In 1886 its pathological causation was a matter of acute controversy, but we learnt by a very few years of operative surgical experience that, whatever other factors might be concomitant, the most important one in the production of optic neuritis was increase of the intracranial tension, and thus it happened that our earliest experience was the strikingly rapid subsidence of the optic neuritis when the skull and dura mater were opened. Therefore it is now possible to dogmatise on this question and to say that in no case of optic neuritis (not, of course, of toxæmic or anæmic origin) should the process be allowed to continue after it has once been diagnosed, and that if blindness results therefrom the responsibility is very heavy on anyone who fails to advise such a simple proceeding as opening the dura mater. As regards the procedure to be adopted, my own experience is that although in rare instances the neuritis may begin to subside after even the first stage of only opening the skull it is, as a rule, necessary to make a free opening in the dura mater to effect this purpose. One reservation must be made, that in cases where the tumour directly involves the optic tract the specially delicate anatomical structure of the optic tract may negative the attaining of this otherwise invariable result.

In predicting what will be the condition of vision after surgical treatment of the optic neuritis everything depends upon the care with which the ophthalmoscopic appearances of the disc are interpreted. Yellowish-white stippling, patches of exudation, or opal white atrophic changes, especially when associated with macular figures, all indicate that the secondary changes in the disc are likely to be permanent, and therefore in proportion to their development so the vision will be impaired, whereas when the loss of vision has been dependent simply on the swelling of the disc then not only is the sight saved but largely improved. For some further discussion of this most important point from the point of view of the ophthalmologist I would refer to Mr. Leslie Paton's recent analysis of the Queen square cases which contains many of the results of my operations.

One more point must be mentioned in connexion with optic neuritis because although of more importance in diagnosis than technical procedure I find it is of the utmost value in indicating to the surgeon on which side he should operate. I refer to the localising value of the incidence of the optic neuritis. Varying statements have been made on this subject from time to time—namely, (*a*) that the optic neuritis begins on the side of the lesion; (*b*) that it begins on the opposite side of the lesion; (*c*) that sometimes one thing happens and sometimes the other according to the position of the lesion in the skull—for example, whether above or below the tentorium and according to the nature of the lesion. I wish to lay down the proposition drawn from an examination of my own cases of intracranial tumour that the optic neuritis commences on the side of the lesion. I am quite aware that true exceptions may yet be found to this rule, but I would point out that some of the exceptions hitherto described have not been real; that in any given case it is not a question merely of the number of dioptres of swelling of the disc, but it is also a matter of the anatomical changes in the disc; and, finally, that by the time the patient comes under observation the disc on the side of the lesion may be actually subsiding into decadent conditions at a time when the opposite disc is rising into its maximal swelling.

To sum up, then, during the past 20 years we have learnt that although the old procedure of de Wecker of incising the swollen sheath of the optic nerve in the orbit is of no avail we can with certainty avert blindness by opening the subdural space early in cases of intracranial disease. The opening is to be made preferably in the basal temporal region of the right side—that is, assuming that no attempt is made to attack the disease itself.

CURATIVE SURGICAL PROCEDURES.

If the operation is undertaken for the purpose of effecting a cure we have to consider (1) what is the nature of the disease; (2) what loss or aberration of nerve function it causes; (3) whether if the lesion be wholly extirpated there will be a recovery from the disorder of function; and (4) whether any loss which may have been present before operation will be made permanent by the necessary extirpation of particular regions of the brain. On points like the last it is evident that we cannot give a satisfactory opinion until we know precisely, first, what parts of the central nervous system alone contain the representation of movements or the record of sensation, and consequently of what parts does destruction entail permanent loss of function. In other words, we require to learn from the cerebral physiologist in what circumstances and to what extent can we get *compensation* of function when various parts of the (*a*) cerebrum and (*b*) cerebellum are destroyed.

(*a*) As regards the cerebrum, from the clinical records we can generalise that special motor functions cannot be restored if the whole of their cortical representation be removed. The same thing is probably also true of the special senses and certainly is true of the hemianopic representation of sight. Succinctly stated, this amounts to the generalisation that compensation is not possible after the destruction of middle level centres. (See Fig. 1.) The higher sensory representations and *a fortiori* the intellectual functions are, on the contrary, not permanently abrogated by the destruction of any one part of the cerebral hemisphere. The net conclusion, however, must be that as little injury as possible should be done and no more removed than is absolutely necessary, it being always understood that this does not apply to the skull but only to the nerve structures. The opening in the skull must always be free to allow of a proper survey of the brain.

(*b*) As regards the cerebellum, this question of compensatory power is no less interesting in the study of a homogeneous structure like the cerebellum, and has assumed a particular importance in the present subject because of Professor Frazier's proposal to extirpate the lateral lobe of the cerebellum in preference to pushing it aside by displacement for the purpose of reaching deep-seated tumours. My own experience is against such extirpations for convenience. In fact, I regard them as an unnecessary mutilation, though quite admitting that in the process of removing a large tumour in that region the cerebellum is considerably bruised when so pushed aside. I ought to add that although I have removed a considerable number of lateral recess cerebellar growths I have never found it necessary to do more than compress the cerebellum aside. (See Fig. 2.)

As to whether there is loss of function from such displacement involving bruising of the cerebellum I have followed up the longest surviving case that I could find in the Queen-square series—namely, one of cerebellar tumour and cyst combined, which I operated on 11 years ago, when the patient was a boy of 14 years. He is now a healthy young man of 25 years. In this case the tumour was a large one, situated in the right lateral lobe of the cerebellum, which was consequently markedly compressed, and probably the dentate nucleus of that side was also affected. The only indication of loss of physiological function that he now presents is a slight unsteadiness of the hand when he is particularly fatigued, as, for instance, after a long bicycle ride. He has plus tension of the normal cerebro-spinal fluid. As far as the cerebellum is concerned, whether this remarkable recovery is due to restoration of function of the bruised portions or to compensation from the uninjured part cannot yet be determined with certainty (I believe the former), but the conclusion I would draw is that we should preserve as much as possible of every portion of the encephalon which is not absolutely shown to be diseased.

At any rate, cases either cerebral or cerebellar dealt with on these lines show a remarkable power of recovery of function.

CONSIDERATION OF THE DETAILS OF OPERATIVE PROCEDURE.

(*a*) *Previous preparation.*—The general preparation of the patient by dieting, enemata, &c., is the same as for all operations. In a few instances I have found calcium chloride of probable service in cases where oozing from the bone or superficial tissues was to be expected, as in cases of penetrating endotheliomata of the skull. The head and cavities in relation to it having been thoroughly disinfected for two or more days with sublimate and carbolic acid, the patient is placed on the table in such a position that while the head is elevated to diminish the pressure in the venous sinuses the shoulders are also slightly raised, so that the glottic respiration is not interfered with. If the operation is to be on the cerebellum the patient is placed on his side with the uppermost arm drawn downwards. By these simple means complete access can be gained for any operation on the encephalon without subjecting the patient to constraint which affects both the circulation and the respiration. This question of posture of the head is no mere matter of convenience to the operator: it is an extremely serious one to the patient for the satisfactory performance of the operation and is only to be secured by having a suitable head-rest, such as the fork-rest of Professor Frazier or the one I use.

(*b*) *Anæsthesia.*—Of the general anæsthetic substances at our disposal, therefore, there are at the present time two for practical discussion—namely, ether and chloroform. Of these two, numerous experiments on animals in 1883–85 proved to me the striking disadvantages of ether, in spite of its greater safety, which it owes to its far lower physiological toxicity on nerve tissues. Apart from this specific difference the most important contrast between the two substances is due to their respective effects on the blood circulation. Ether directly causes, besides a rise of the blood pressure, a notable increase of the blood venosity and therefore much additional and troublesome hæmorrhage. In its later effects—that is, on recovery—it causes excitement, as well as in many cases notable headache and, of course, vomiting. Ether I regard, therefore, as inadmissible as an anæsthetic in operations on the central nervous system; but in saying this I must not be thought to be criticising my colleagues, especially American surgeons, who have accomplished most brilliant results under ether narcosis. Chloroform, *per contra*, causes a fall of blood pressure with relatively less blood venosity, although this is by no means absent, as will be seen below. It therefore does not aggravate the bleeding or embarrass the respiration by causing bronchorrhœa. Chloroform, however, as already stated, is more dangerous. It kills by paralysis of the respiratory centre as often as, or more often than, by paralysis of the heart, while all cases of increased intracranial tension (as is now well recognised) are liable to die at any moment from sudden paralysis of the respiratory centre. In the literature of the early days of cerebral surgery may be found instances of death on the operation table. I have no doubt that these were due to failure of the respiratory centre owing to a dose of chloroform having been given which, though perhaps not necessarily lethal in an ordinary case, was fully so to a patient whose bulb was hampered by previous tumour pressure. Chloroform, therefore, must be used with caution in the surgery of the nervous system to avoid giving a dose which might bring about fatal arrest of the respiratory centre.

The immediate problem is how to regulate the dosage of chloroform, and let me say in passing that the whole of my consideration of this question is applicable to all operations and not only to those on the central nervous system. Yet, curiously enough, because the early efforts of Snow, Clover, and others to obtain the administration of such a drug in known quantities were not entirely successful, the present haphazard and dangerous method of unknown dosage became customary and universal. At the original suggestion of Dr. A. Waller I obtained on *July 10th*, 1901, from the Council of our Association, the appointment of a research committee to secure data for the administration of chloroform in known doses, commencing with its precise quantitative determination. The results so far obtained have already proved of notable value. The committee has found that less than 2 per cent. of chloroform vapour in the atmosphere breathed by a patient is enough to produce deep narcosis and that a much smaller dose is required to maintain unconsciousness to pain. Various apparatuses have been devised to give known percentages of chloroform. Of these I have worked practically entirely with Mr. Vernon Harcourt's.

Much has been written on the subject of chloroform administration, but I must state categorically what I believe to be the most profitable way in which it can be used in operations on the nervous system and how its disadvantages can be mitigated or avoided. If the mask of the inhaler be made to fit by wet aseptic towels the amount of the dose

Address in Surgery

ON

THE TECHNIQUE OF OPERATIONS ON THE CENTRAL NERVOUS SYSTEM.

Delivered at the Seventy-fourth Annual Meeting of the British Medical Association on August 22nd, 1906,

BY SIR VICTOR HORSLEY, F.R.C.S. ENG., F.R.S.,

LATE CHAIRMAN OF THE REPRESENTATIVE MEETING OF THE BRITISH MEDICAL ASSOCIATION; SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON, AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, LONDON, W.C.

[Sir Victor Horsley commenced his address by defining the limits within which he intended to speak. 20 years ago, he said, he had shown at a meeting of the Association the first three patients upon whom he had operated at the National Hospital for the Paralysed and Epileptic for intracranial disease. During the interval further experimental research on animals and clinical observations upon human beings had confirmed the soundness of the treatment that he then laid down; and in his address he proposed to analyse his cases at the National Hospital and to show that an accumulation of facts now afforded a ready answer to many important questions of diagnosis and prognosis. He continued:—]

THE RESPONSIBILITY OF THE SURGEON.

I must first briefly allude to the responsibility of the surgeon in the treatment of diseases of the central nervous system. As in all special branches of medicine and surgery which are in a process of evolution it is not easy to assign credit or blame when the course of treatment pursued is respectively successful or unsuccessful; but so long as our powers of diagnosis remain as imperfect as they are so long will the vulgar error of regarding surgical treatment as a *dernier ressort* be committed. This question—namely, When should medicinal treatment be given up and operative treatment substituted?—has been raised again and again and hotly discussed in connexion with many diseases, notably appendicitis. In 1890, hoping to secure a more logical and definite pronouncement on this fundamental point at the International Medical Congress, I proposed that in cases of Jacksonian epilepsy and other syndromata which suggested the existence of gross organic disease of the brain a definite probationary period of medicinal treatment should be agreed upon and that in an elementary case where no urgent symptoms like optic neuritis existed surgical treatment should be employed after thorough drug medication had been energetically applied for about six or eight weeks and cure had not appreciably resulted. No conclusion, however, was arrived at. Again, in 1893 I was unable to get an expression of opinion on this point, although Dr. Allan Starr in his well-known work on "Brain Surgery," has also formulated the conclusion that the surgeon should be invited to consultation in the case after about three months' medical treatment had been unsuccessful. Although such a course is in general the practice at the Queen Square Hospital, this view of the situation unfortunately has not yet been discussed in the profession. Even in the present year I have been asked to operate on a patient with a lateral tumour of the cerebellum who had been known to have optic neuritis for nine years, and last year I did operate on such a patient who had been known to have optic neuritis for 13 years. It is, of course, perfectly ridiculous to include such cases in surgical statistics purporting to be a scientific study of this subject, and I only mention them to show what extraordinary ideas still prevail of our responsibility towards the victims of diseased conditions when such happen to constitute what are termed new subjects in medicine and surgery.

Assuming now that in a given case surgical treatment is considered advisable, the question immediately arises for what precise purpose is it to be employed, for all treatment, medical or surgical, is either palliative or curative. These two aspects of the matter require separate consideration.

PALLIATIVE SURGICAL PROCEDURES.

It is a prominent characteristic of intracranial disease that (1) it is liable to produce optic neuritis, which customarily ends in total blindness; and (2) it may concomitantly cause severe headache and vomiting, all of which symptoms are dependent upon pressure and can be completely palliated or wholly removed by making a sufficiently free opening in the skull and dura mater.

Optic neuritis is a condition which, owing to its causing blindness, is of such vital importance to the interest of the patient, and so to the community, that it merits full attention. In 1886 its pathological causation was a matter of acute controversy, but we learnt by a very few years of operative surgical experience that, whatever other factors might be concomitant, the most important one in the production of optic neuritis was increase of the intracranial tension, and thus it happened that our earliest experience was the strikingly rapid subsidence of the optic neuritis when the skull and dura mater were opened. Therefore it is now possible to dogmatise on this question and to say that in no case of optic neuritis (not, of course, of toxæmic or anæmic origin) should the process be allowed to continue after it has once been diagnosed, and that if blindness results therefrom the responsibility is very heavy on anyone who fails to advise such a simple proceeding as opening the dura mater. As regards the procedure to be adopted, my own experience is that although in rare instances the neuritis may begin to subside after even the first stage of only opening the skull it is, as a rule, necessary to make a free opening in the dura mater to effect this purpose. One reservation must be made, that in cases where the tumour directly involves the optic tract the specially delicate anatomical structure of the optic tract may negative the attaining of this otherwise invariable result.

In predicting what will be the condition of vision after surgical treatment of the optic neuritis everything depends upon the care with which the ophthalmoscopic appearances of the disc are interpreted. Yellowish-white stippling, patches of exudation, or opal white atrophic changes, especially when associated with macular figures, all indicate that the secondary changes in the disc are likely to be permanent, and therefore in proportion to their development so the vision will be impaired, whereas when the loss of vision has been dependent simply on the swelling of the disc then not only is the sight saved but largely improved. For some further discussion of this most important point from the point of view of the ophthalmologist I would refer to Mr. Leslie Paton's recent analysis of the Queen-square cases which contains many of the results of my operations.

One more point must be mentioned in connexion with optic neuritis because although of more importance in diagnosis than technical procedure I find it is of the utmost value in indicating to the surgeon on which side he should operate. I refer to the localising value of the incidence of the optic neuritis. Varying statements have been made on this subject from time to time—namely, (*a*) that the optic neuritis begins on the side of the lesion; (*b*) that it begins on the opposite side of the lesion; (*c*) that sometimes one thing happens and sometimes the other according to the position of the lesion in the skull—for example, whether above or below the tentorium and according to the nature of the lesion. I wish to lay down the proposition drawn from an examination of my own cases of intracranial tumour that the optic neuritis commences on the side of the lesion. I am quite aware that true exceptions may yet be found to this rule, but I would point out that some of the exceptions hitherto described have not been real; that in any given case it is not a question merely of the number of dioptres of swelling of the disc, but it is also a matter of the anatomical changes in the disc; and, finally, that by the time the patient comes under observation the disc on the side of the lesion may be actually subsiding into decadent conditions at a time when the opposite disc is rising into its maximal swelling.

To sum up, then, during the past 20 years we have learnt that although the old procedure of de Wecker of incising the swollen sheath of the optic nerve in the orbit is of no avail we can with certainty avert blindness by opening the subdural space early in cases of intracranial disease. The opening is to be made preferably in the basal temporal region of the right side—that is, assuming that no attempt is made to attack the disease itself.

respiration, the maintenance and control of the blood pressure, and for the maintenance and control of the temperature of the body. Hence the only way in which we can adequately examine into the subject is by systematic discussion of these several points.

Fortunately the clinical investigation of the first—the alteration of the intracranial tension—has been rendered more easy by reason of the procedures adopted during the last 13 years. In 1893, at the discussion in the Section of Surgery of this Association at Newcastle, I pointed out that the early statistics of intracranial operations showed that the majority of deaths occurred from a severe degree of shock which could be in great part avoided by dividing the operation into two stages, the interval between them being about five days.

The first stage consisted of the opening of the skull, the second of opening the dura mater and removal of the lesion. On the same occasion I also drew attention to the fact that, although at the second stage the dura mater was opened, the removal of the tumour was often attended by relatively little shock. Subsequent experience has fully confirmed these statements and shown that it is, in fact, the opening of the skull which causes most general depression of nerve energy and most alteration in the circulation.

[The lecturer then briefly dealt with the methods of opening the skull, pointing out that the indications were to employ little vertically applied force, and to avoid as far as possible all pressure on the brain and dura mater; he then passed to the next practical question—the influence of the region opened.]

ALTERATION OF INTRACRANIAL TENSION.

(a) *Influence of region of skull opened.*—This introduces a very important point which was first raised by Duret some 30 years ago and has attracted the attention of most surgeons who have more especially operated on the cerebellum. It is obvious that, inasmuch as the nerve centres of organic representation are situated in the posterior fossa of the skull, opening this region might theoretically be expected to cause more shock symptoms than the opening of other parts. No statistics can give a dogmatic explanation of this or any other clinical matter, and in fact every case forming the material for our present statistical analysis in which death occurred from shock after the first stage (six of the total number of cases) was complicated by the pressure of the lesion being only partly diminished, while in two instances there was, in addition, persistent hæmorrhagic oozing; but on taking all the cases together they give the following result, which is sufficiently demonstrative:—

	Proportionate ratio.
"Motor area"	1 death in 27 operations
Parietal and post-parietal regions	1 „ 19 „
Frontal region	1 „ 15 „
Temporal region	1 „ 12 „
Cerebellar region	1 „ 10 „

If, therefore, a line be drawn from the frontal eminences to the occipital protuberance it is obvious that more shock results from operations below that line than from above and also as we proceed from the frontal to the cerebellar pole of the encephalon. Duret's conclusion was that pressure applied to the frontal regions specially produced lethal effect by direct transmission to the medulla along an axis parallel to such a line and I shall show how such mechanical effects can, as far as possible, be avoided during operations on the basal parts of the brain.

(b) *Production of von Bergmann's œdema cerebri.*—The surgery of the central nervous system has been enriched by many contributions that have been made to it by von Bergmann, but on no point more particularly than that of the causation and frequency of œdema of the nerve tissues (see especially his "Kopfverletzungen" and later, "Die chirurgische Behandlung der Hirnkrankheiten," 1889, p. 118, et seq.). The readiness with which the cerebrum and cerebellum become œdematous is remarkable, but the circumstances in which it happens are not at all easy to understand and the facts of a large series of cases do not fall into line with von Bergmann's generalisation—namely, that œdema necessarily occurs whenever the skull is freely opened. Thus, after the second stage of an extirpation in which the skull has been very freely opened and a tumour removed there may be only a very moderate degree of œdema of the hemisphere operated upon, which, like all traumatic œdema of the brain, arrives at its maximum in from three to four days and disappears without any complication. On the other hand, when the skull has been freely opened in the first stage and the dura mater left intact, if the pressure of the growth is considerable, that may be accentuated by the development of a markedly œdematous condition around the focus of pressure. It is, of course, quite comprehensible that this is owing to the fact that a slight relative increase of tension may unfavourably affect the walls of the cerebral blood-vessels which are still under compression and bring about a Cohnheim effect. That this does occasionally occur is proved by the very rare phenomenon of translation of the red blood corpuscles into the œdematous tissue.

(c) *Exploratory operation.*—The statistics of the National Hospital for the Paralysed and Epileptic throw a good deal of light on this subject and show that unrelieved pressure is a matter of great practical importance in respect of ordinary palliative operations performed to abolish optic neuritis and relieve the headache—in short, to the procedure to which Professor Cushing has recently given the name of "decompression" operations. I will take this point now. Thus, of 13 cases which died from shock after the second stage, in seven by reason of failure of topographical diagnosis, the pressure was not relieved directly over the seat of the lesions, whereas in six cases in which a tumour of the brain was diagnosed and correctly localised, but in which removal was not attempted owing to the size of the growth and other reasons, no patient died. A comparison of this kind is sufficient, I think, to warrant the statement that the risk of an operation for decompression is greater if the opening for the relief of pressure is not made directly over the lesion. Precisely the same point is borne out with even greater distinctness by the figures showing the relative risk of operating with and without a correct diagnosis. Thus, of 79 cases in which a correct diagnosis was made and the tumour successfully removed, seven cases died from shock—a little over 8 per cent.; whereas in 16 cases of tumour which were incorrectly diagnosed, and consequently not removed, six cases died from shock—approximately 37 per cent. It is, perhaps, worth while adding that practically in all these latter cases the tumour was a glioma or gliomatous sarcoma—that is to say, a diffuse growth the diagnosis of which is always the most obscure, and at the same time a form of neoplasm in which circulatory changes and œdema are always liable to occur. I think that these data enable us to form a more or less correct estimate of the risk of an exploratory operation in cases of doubtful diagnosis.

TREATMENT OF SHOCK.

As I have suggested above, the treatment must be arranged according to the symptoms which threaten life, and those may be grouped according as they affect (a) the respiration, (b) the circulation, and (c) the body temperature. Depression or aberration of special nerve functions—for example, motion, sensation, &c.—need not be a source of anxiety, as if the centres of organic life are restored recovery of the others will certainly follow in proportion to the extent to which their representation has been preserved.

(a) *Respiration.*—The embarrassment of the respiratory centre in a stage of shock shows itself in increasing degrees of severity as follows: (1) shallowness of the respiratory movement; (2) periodicity and grouping of the respiratory movements; and (3) typical Cheyne-Stokes respiration. These changes are best dealt with by inhalations of oxygen until the effect of nutrient enemata (*vide infra*) begins to make itself felt, but it is above all in depression of the respiratory centre that strychnine is of use in combating shock. In speaking thus favourably of strychnine I nevertheless agree with the elaborate and useful work of Dr. Crile on this subject and believe that in many cases strychnine is used too empirically, too freely, or with undue reliance on its powers, and that in repeated doses it has a depressant action on the circulation. As a stimulant of the bulbo-spinal centres strychnine is, of course, unrivalled, and when any marked alteration in the rhythm of the respiratory centres shows itself a small dose should be given hypodermically, but for the above-mentioned reasons it does not seem advisable to give such a drug beforehand, as is sometimes done either immediately previously to the operation or at the end thereof, with the idea of anticipating difficulties resulting from shock. It is also not to be forgotten that the usual functional depression of the respiratory and the cardiac centres which immediately precedes chloroform vomiting is particularly marked in these operations and often causes unnecessary alarm.

(b) *Circulation.*—In considering the depression of the given will be under complete control. With the dose commencing at 0·5 per cent., and rising in from one to two minutes to 2 per cent., the patient ought to be ready for operation after from five to eight minutes. If the initial narcosis be complete no adverse event—for example, vomiting—will occur. If it be incomplete when operation is commenced various drawbacks will appear. This is, of course, well recognised as a general principle by anæsthetists, but is so salient a point as to deserve repetition.

Having now, by means of the Harcourt or other regulator, the power of giving known doses, we ought to arrange the narcosis strictly according to the nerve excitations it is intended to drown and so avoid contributing to the patient's discomfort by giving unnecessary quantities of the drug. As a rule, the amount of 2 per cent. is given for about five minutes before the incision of the skin and reflection of the flap which constitute the maximal pain period of the operation. This completed, the dose can be lowered by pushing the tap back and the bone be removed at 1 per cent. As the dura mater is a sensitive membrane supplied by the fifth cranial nerve the dose should be somewhat raised just previously to its incision to prevent reflex starts or movements on the part of the patient. As soon as the dura mater is opened the encephalon can be dealt with without causing any pain except if the course of the fillet or one of the peripheral sensory cranial nerves be accidentally irritated. Consequently all this part of the operation is done under less than 0·5 per cent. of chloroform in the air respired, an amount which, of course, is far below that required in the induction stage. Indeed, in many cases (the edges of the wound being as usual thoroughly protected by gauze) the chloroform can be entirely shut off, the longest period that I have been able to do this for being 20 minutes. This, however, was a case of a cerebellar tumour in a child and I have never been able in the adult to exceed 12 or 15 minutes before the return of the reflexes of the limbs necessitated the renewed administration of the drug. After the encephalic lesion is dealt with the percentage always should be raised to about 0·7 or even 1 per cent. to provide for the insertion of the sutures in the skin, as naturally that is a strong pathic stimulus. Finally, this percentage is continued to the commencement of the dressing to prevent the accident of vomiting occurring before the protecting rubber bib can be applied.

(c) *Maintenance of the body temperature.*—The general anæsthetic has, of course, a high degree of power to lower the temperature of the body and therewith to emphasise the shock of the operation. For this reason I think that all operating rooms should be at a temperature of not less than 75° F., and that the operating table should be provided with a suitable hot-water bed. While, however, cooling due to the anæsthesia can thus be readily combated, my experimental work of the last 20 years on both the carnivora and monkeys has convinced me that to maintain the physiological energy of the central nervous system and prevent shock thereto it is necessary during all operative procedures on the skull and its cavity to prevent cooling by radiation from the brain exposed in the wound. The wound therefore should be constantly irrigated, usually with a solution of sublimate of 1 in 10,000 strength, or with saline solution. These lotions are put into the irrigator at a temperature of 115°, the use of the hot irrigation fluid being not only to prevent cooling of the nerve centres but to arrest capillary and arterial hæmorrhage.

(d) *Hæmorrhage.*—The first general principle is the recognition of the fact, originally established by Cohnheim's researches, that as few vessels as possible should be obstructed; and, again, experiments on animals show that in encephalic surgery this principle must be followed as closely in the case of the veins as in the case of arteries. For instance, in the monkey the blocking of the large temporo-sphenoidal vein and the most anterior external occipital vein produces softening of the posterior part of the hemisphere. In pursuance of this principle, where it is necessary to remove large portions of the brain, the branches of vessels to be divided should be severed as far as possible from the trunk. A few points in detail must now be discussed according to the nature of the vessel.

From time to time it has been proposed to tie the main arteries—for example, the carotid—with the view of producing a large control of the blood flow from the cerebral arteries. But a thorough consideration of the cases in which this has had to be done by reason of operative necessities has convinced me that it is a measure to be avoided as far as it possibly can be. For instance, when ligature of the carotid has been found necessary in the case where a portion of the hemisphere has been partly displaced and compressed to gain access to a basal tumour, serious and even fatal secondary œdema and softening have proved the adverse influence of this proceeding. On the whole, I cannot suggest anything better than the original plan of tying all the arteries around the lesion before extirpating it; and inasmuch as all arterial supply of the encephalon is necessarily from below upwards, it is better to commence the excision of a lesion by beginning the incision in the brain below and carrying it upwards and towards the mesial plane.

Although it is necessary that every bleeding artery should be secured by ligature, it is remarkably easy to arrest capillary oozing and arteriole oozing from the brain by the simple means of hot irrigation. The temperature of the fluid should not exceed 115° F.—that is, about 46° C., but it must not fall below 110° F. or 43·5° C. If a larger irrigator be used it is practically an easy thing to keep the fluid at the desired temperature on account of its mass and it is gratifying, especially in a cerebellar wound, to see the oozing gradually cease during the steady flow from the irrigator "hose" pipe.

One of the most striking features of the physiological action of chloroform on the mammalian animal is that it soon (from 10 to 20 seconds) causes a marked fall in blood pressure. Consequently when a lesion is about to be extirpated and there is reason to expect considerable oozing, or when the brain is obviously turgid with congestion, I always ask that the chloroform percentage should be raised for, say, from a quarter to half a minute to 1 or 2 per cent. This at once induces a convenient, proportionate, and, of course, temporary anæmia.

The consideration of capillary oozing and hæmorrhage brings us logically to the question of bleeding from the venous system, because capillary oozing is so dependent on the venous pressure. The same steps, therefore, which diminish the latter will also reduce the former. All bleeding from the veins and sinuses in bone can be immediately and absolutely certainly arrested by plugging with wax if the periosteum round the hole is completely removed. No difficulty, therefore, should ever arise from hæmorrhage from this cause. It is otherwise with wounds of the sinuses and Pacchionian bodies and venous lakes in the dura mater. The bleeding from these, however, no matter how severe, is immediately controlled by pressure with the point of an instrument, while the opening is closed by a fine lateral suture on a round needle in the usual way. The principal veins if necessary are, of course, ligatured like arteries by passing a round needle beneath them, and there only remain, therefore, for consideration the control and arrest of venous oozing.

[*Sir Victor Horsley here referred to the influence of oxygen in the control of venous and capillary oozing and then proceeded to discuss:—*]

SHOCK.

Death occurring within the first 24 to 48 hours after the operation is from what is termed "shock." Since shock or sepsis are practically the only causes of death which can be provided against, the prevention of shock lies at the root of successful prognosis as well as of further improvement in surgical technique. I quite agree with Crile, who has done so much to elucidate this all-important question, that we should discriminate between shock and collapse; and that while collapse is a temporary accident in which the patient's nerve centres are capable of being revived by ordinary clinical means, shock, on the other hand, is a post-operative condition which deepens after the operation for a variable period and which if it terminates fatally destroys life, as a rule, within 24 hours. It is this dangerous phenomenon which we must now discuss.

From observation of the condition of patients after all kinds of operations it is evident that the phenomena of dangerous shock differ according to the part of the body operated upon, according to the condition of the patient before the operation, the concurrence of accidental hæmorrhage, &c. The alteration of the intracranial tension which is produced by opening the skull of itself necessarily causes shock after encephalic operations in a manner which is somewhat different from that caused by other operations. Therefore I think its treatment must also be different. The nervous system is responsible for the maintenance of the encapsulated tumour, every attempt ought to be made to exert a leverage or traction, so that the direction of the force is always outwards.

[These principles underlying the avoidance of shock having been fully discussed, we may turn to the question of septic infection, said Sir Victor Horsley, pointing out that when many surgeons can show an unbroken record of successful operations for the radical cure of hernia or for appendicitis in the cold stage it is not completely realised how very different should be our estimate of the proclivity of the central nervous system to invasion by septic micro-organisms and the extremely feeble degree of its resisting powers. Personally he believed that the present-day precautions are sufficient at the time of operation, especially if the irrigation fluid used be a weak antiseptic lotion; that for the subsequent dressings it is essential to use an antiseptic (he had only complete confidence in a mercury salt), and that so long as the cerebro-spinal fluid continues to escape the most vigorous disinfection of the skin and frequent changing of the dressings must be carried out. He concluded by re-asserting his view that the less drainage employed the better and consequently that every effort should be made to close the skin wound as early as possible. He continued:—]

DISPLACEMENT OF THE BRAIN.

With these general considerations before us there remains the discussion of particular procedures. One of the most important of these is displacement of the brain which must be resorted to to reach tumours at the base. I mean displacement of the lobes or regions. My first attention to this subject was drawn by being requested in 1889 to operate on a tumour pressing on the front of the optic chiasma and for this purpose I raised the frontal lobe but found that the tumour was really a cystic adeno-sarcoma of the pituitary gland and was inoperable. To facilitate the elevation of the frontal lobe some of the veins entering the longitudinal sinus therefrom were ligatured. On the death of the patient some years later I found that there was considerable softening of part of the frontal lobe in the area drained by these veins and not directly implicated by the tumour. This and subsequent evidence referred to above led me to the following conclusions, which I have repeatedly made use of and found of service, especially in ten cases of operation on the pituitary body. The cerebral hemisphere is anchored by emissary veins to the dura mater at various points (see Figs. 2 and 3): (1) in the mesial plane—that is, to the longitudinal sinus; (2) laterally, chiefly by the temporo-sphenoidal vein to the lateral sinus opposite the asterion; (3) to a less degree by the external occipital vein; and (4) by the anterior temporo-sphenoidal vein, both of which last are small vessels but being almost terminal require to be respected none the less. The hemisphere can be readily compressed upwards by inserting a flat spatula cautiously beneath it and between the veins just described. The next question, of course, is, What happens to the hemisphere compressed? This entirely depends on the mode of compression. If the compression is, as it should be, gradual, the soft nerve tissues soon mould, with very little internal derangement; but it is easy to produce, with too much and too rapid application of pressure, laceration of, and ecchymotic oozing between, the fibres of the corona radiata. Such compression contusions of the basal portions of the hemisphere are relatively unimportant, because they relate to portions of the cortex of which the function is either readily compensated when lost or of very wide representation. The inspection of the deep parts of the skull by displacement of portions of the brain entails trouble to the assistant, because it is certainly disadvantageous to move the retractor when once properly in position. So far I have spoken of the cerebrum. I think that precisely the same principles should prevail in the case of the cerebellum. With this procedure properly applied to the temporal lobe it is remarkable how much can be seen and correctly examined. With a good illumination the crura cerebri, the circle of Willis, the pituitary body and internal carotid, the second and third nerves come into view. I have in two cases after removal of a pituitary tumour inspected the base of the brain further by means of a small rhinoscopic mirror placed in the sella turcica; and it is very easy by continued but gentle pressure with a copper spatula, or with a spatula of suitable size and with a strong headlight, to inspect the lateral region of the cerebellum and medulla oblongata with the issuing nerves. (See Figs. 1 and 2.) For these reasons I venture to take exception to the step of removing portions and lobes of the encephalon if these impede the approach to the lesion.

THE VENTRICLES.

In this connexion—namely, procedures necessary for the examination of the deeper portions of the brain—a few moments must be devoted to the matter of exploration of the ventricles. Considering that for 1400 years (as we know historically) the lateral ventricles were looked upon as the most important part of the brain, inasmuch as the animal spirits, or, as we should now say, nerve energy, originated therein, it is not surprising to find that special danger was supposed to attend their opening or surgical interference. Undoubtedly their continued drainage exposes the patient to the particular risk of sepsis, but apart from this there is no reason why they should not be freely dealt with like other parts of the brain, opened and portions of their wall removed as the case may require, provided that one precaution is taken, namely that blood is prevented from flowing into the ventricular cavity. This, of course, may be obviated at the time of operation by a simple plug and when the removal of the lesion is completed a temporary tampon is left in for 24 hours, by which time all the oozing vessels are thrombosed. I may, perhaps, on this question draw attention again to my paper of 1893, because the case therein referred to of death by intraventricular filling was an instance of persistent oozing gradually forcing its way through the softened roof of the unopened ventricle.

PROCEDURES IN THE TREATMENT OF MALIGNANT DISEASE OF THE ENCEPHALON.

The analysis of the cases at the National Hospital for the Paralysed and Epileptic also brings out in very strong relief the fact that where the technique of intracranial operations fails most is the treatment of malignant disease. This, therefore, will fitly form the last chapter of our considerations. All tumours which, growing from the meninges, penetrate the brain, or which are encapsulated, such as fibromata, myxomata and endotheliomata, tuberculomata and gummata, can all be excised with a good permanent result. The comparison between simple and malignant disease is well shown in the accompanying table of 55 tumours, cases in which the patients' histories have been followed up to date.

Cases at the National Hospital for the Paralysed and Epileptic. Recurrence Table of 55 Tumours.

		Cases.	
Glioma	19	23	Recurrence within 2 years, 20.
Sarcoma	4		
Endothelioma		8	1 recurrence 3 years later; died from heart disease, valvular. 7 alive well, longest 5 years.
Tuberculous ...		4	2 died within 3 months from tuberculous meningitis. 2 alive well, longest 7 years.
Gumma		8	No recurrence.
Fibroma		4	No recurrence.
Cysts		5	No recurrence.
Adenoma ...		Pituitary 3	1 recurrence.
Adeno-sarcoma			

But unfortunately a considerable proportion of cases of cerebral tumour are essentially malignant and by reason of their diffusing through the nerve tissues are very difficult to deal with so as to produce a complete and radical cure. These are the gliomata or glio-sarcomata. One elementary point of difficulty arises from the fact that they not infrequently reach a considerable size before they produce sufficient symptoms to render a topographical diagnosis accurately possible. Further, pathological anatomy does not yet tell us how to classify these growths or how to determine what is their exact point of origin; consequently it is very difficult to attack systematically their growing focus or plan correctly the complete extirpation of the infected tissues. Further, the regions of the brain surrounding the tumour are commonly œdematous, and this introduces a fresh difficulty—namely, to decide between the infiltration of the brain tissue with neoplastic growth and with simple œdema respectively. The Queen-square series of cases in the foregoing table show that recurrence of malignant disease was observed in no less than 20 out of 23 instances. I have on several occasions attempted, with but very partial success, to obtain by extirpating such recurrences the same striking result as Bramann in his classical case, but undoubtedly the treatment of this class of disease will not be surgically satisfactory until the diagnosis is so far improved as to make it circulation by shock we must again express our indebtedness to Dr. Crile for having shown that this part of the subject is not merely a question of the central or cardiac maintenance of the blood pressure but to a large extent the lack of influence of the vaso-motor system. I think the beneficial effects of pressure on the surface of the body can be obtained by bandaging the limbs with cotton wool. It remains, therefore, to consider what drug treatment is to be resorted to. As regards cardiac stimulation, that has always seemed to me to be a clinical error. The heart does not require accelerating as a rule but it does require feeding. Undoubtedly repeated enemata (every two hours) of four ounces of beef-tea in which is dissolved Brand's essence or pancreatised milk are the readiest means of beginning to follow this line. If time presses a very small dose of atropine is useful and in cases of peripheral vaso-motor paralysis digitalis is also useful, but its use must be at once stopped if there is any acceleration of the pulse. It is, I believe, of universal experience that, compared to the foregoing drugs, alcohol is not worth mentioning, and as it has very definite depressant after-effects I think its use is to be avoided. A small quantity of strong coffee gives all the psychic stimulation of alcohol without its depressant effects and even if it be vomited within a few minutes benefit results.

Brain of macaque monkey, showing effect of vein ligature for displacement of hemisphere.

(c) *Body temperature.*—In a large majority of cases the body temperature is somewhat lowered but in certain instances, notably in children, one of the shock effects of operation is the losing of heat control and consequently the temperature, instead of falling, rises from the moment the patient is returned to bed. This rise may in a child become hyperpyretically dangerous but can, of course, be, as a rule, like all neurotic pyrexia, controlled by cold sponging the upper limbs.

In leaving the question of shock I desire once more to assert that the main principle of operating on the central nervous system should be the avoidance and prevention of all conditions which lead to shock—namely, cooling and mechanical disturbance of the central nervous system. In respect of the necessity of producing less disturbance or chance of pressure upon the brain beneath, Mr. Spencer found in my laboratory that even slight pressure on the surface of the hemisphere materially affects, in accordance with the principles of Duret, the activity and regular function of the respiratory centre. So, too, in the second stage all the necessary instrumental procedures must be effected with as little pressure upon the brain and nerve tissues as possible. Sponging, for instance, should be avoided unless absolutely requisite; and, indeed, the practice of hot irrigation renders it very unnecessary. In particular, during the separation and extraction of an the head of "puerperal fever" are in the main cases of septicæmia arising as the result of infection introduced from without in connexion with the process of labour and the lying-in, and that this septicæmia is to be prevented by the prevention of this infection. In addition to this, the principal group, there remains a small fraction of cases in which the infection, although introduced from without originally, has remained almost dormant within the body until labour has provided the opportunity for its extension. The theory of a specific epidemic disease has vanished.

The next address was delivered in 1893 at Newcastle-on-Tyne by our revered colleague, Dr. C. J. Cullingworth, who is occupying his leisure from active hospital work by editing the *British Journal of Obstetrics and Gynæcology*. The subject was Pelvic Peritonitis in the Female and the Pathological Importance of the Fallopian Tubes in connexion therewith. The address remains as a landmark in our knowledge of the pathology of salpingitis; it led to the general appreciation by British gynæcologists of the true pathology of perimetritis, as well as to advances in abdominal surgery in the treatment of these cases.

In 1900 an address was given at Ipswich, where I had the honour to be President of the Obstetric Section, by our friend Dr. W. J. Smyly of Dublin, whose work at the Rotunda Hospital is well known to you all, and who has since received the well-deserved honour of knighthood. The subject was Maternal Mortality in Childbed. Its chief importance as a landmark is in its indication of the simplification of antiseptic measures for the protection of parturient women, as, for instance, the abolition of the douche as a routine practice, and in its insistence on the substitution as far as possible of external or abdominal for internal or vaginal examinations during labour. Sir W. J. Smyly does full justice to the pioneers in the fight with puerperal fever, but like Dr. Kidd, and indeed other writers until quite recently, he does not mention the astounding evidence collected by Oliver Wendell Holmes, whose essay on the contagiousness of puerperal fever was placed in my hands by a non-medical friend in my first year as a medical student and has ever since remained in my memory. The profession is indebted to Dr. Cullingworth for having reminded them of the great service which Oliver Wendell Holmes rendered, though with so little immediate fruit.

At the meeting at Manchester in 1902 Professor Sir William Japp Sinclair discussed Carcinoma in Women, chiefly in its clinical aspects. In this address he expressed his firm conviction that the secret of cancer will be discovered (if ever it is) by the study of cancer of the uterus, although his reasons for this view are not very clear. He is less pessimistic with regard to the results of vaginal hysterectomy than many operators and was not at that time in favour of abdominal hysterectomy in these cases.

Such an address as I am requested to give on this occasion should, if possible, deal with some point of general importance and interest rather than of personal investigation or experience, and I can imagine none at the present time so important to the present and future members of the Association as the efforts which are being made to improve the teaching and training of our medical students in practical obstetrics. The faults of our methods of teaching are obvious to every thoughtful person. The difficulty in adequately removing the deficiencies 'is undoubtedly very great. May we first consider some of the most obvious imperfections? These are for the most part due to the difficulty of providing practical clinical teaching. There is no large maternity hospital in London capable of accommodating the students of the various medical schools, for the four lying-in hospitals are primarily charities for the relief of poor women and training schools for monthly nurses and midwives. Queen Charlotte's is the only lying-in hospital which admits medical students or qualified practitioners to its practice. The students, however, who take the month's course obtain clinical teaching and experience of a kind not to be obtained easily elsewhere, but unless the hospital is prepared to give up its principal work—the training of midwives and monthly nurses—in favour of the medical students, its 70 beds, accommodating 1600 in-patients in the year, can only provide the necessary experience for a small number of the students of London. At the present time the practice is attended chiefly by qualified men who, having found out their lack of experience, are glad to make use of the opportunities for instruction to be obtained there. The other three lying-in hospitals provide between them 100 beds but they do not at present admit medical students. So far as teaching is concerned their work is limited to the training of midwives and monthly nurses. The number of women from all parts of the country seeking to be trained as midwives is continually increasing and to meet their requirements the capacity of these lying-in hospitals is fully taxed. All the medical schools and lying-in hospitals have an extern maternity department and in this department the students, under more or less organised supervision, attend poor women in their own homes. Even in the best organised of these maternities the supervision and instruction of the students are very inadequate, for the resident medical officer in charge of them is without that constant guidance and close personal contact with his chief which fall to his lot when working in the wards of a hospital. It is impossible for it to be otherwise and it speaks well for the general standard of practical common-sense that so few calamities occur. When attended by students *who have had the necessary preliminary clinical teaching* these extern maternities provide the most important and valuable training that any medical student can obtain, for, as in private practice, he is then placed almost entirely on his own resources. At any time he may have to deal with one of the sudden emergencies of midwifery, and so he begins to acquire that feeling of personal responsibility for the direction and management of the case which it is so difficult to arouse in the student while at work within the hospital where every important detail is supervised by the responsible officers. Thus, invaluable training is at hand for every student in the maternity districts and their responsibilities in degree and in value are not exceeded by those of any house surgeon or house physician—offices which can only be held by a small minority of the best students.

Another factor which has delayed the provision of adequate teaching in obstetrics, not only in England, but probably in other countries, is the old ingrained idea that the process of labour is a simple function of nature, requiring for the most part a competent nurse only, and that the practitioners of obstetrics, although recognised in theory as of equal standing, are to be looked down upon in comparison with their colleagues in the other great branches of medicine and surgery. As the result of this, both in teaching and in examinations, the study of obstetrics has been relegated to a position totally unworthy of its immense importance to the practitioner and to the national welfare.

As Dr. W. R. Dakin pointed out in his excellent inaugural address before the Obstetrical Society of London last year, if only the scourge of puerperal septicæmia can be removed childbed will be robbed of one of its principal terrors, and this long-desired consummation will be nearer its accomplishment when our students are taught practically in the lying-in wards the application to midwifery of the general principles of antisepsis.

As shown in the report of a committee of the General Medical Council just published it is still common in many places for students to be permitted or even encouraged to attend their maternity cases before they have had any adequate instruction in those general principles of medicine and surgery upon which the whole practice of obstetrics is based.

Another defect in the teaching is due to the fact that the lecturers frequently have had little experience in the practice of obstetrics. It is considered essential for the lecturer on medicine, surgery, or indeed any other special subject, to be a man of wide clinical experience and to be in charge of wards devoted to the care of patients suffering from those particular diseases upon which it is his duty to lecture. In obstetrics it is otherwise; the lecturer presides over no obstetric clinique and has often had but little experience. He is an obstetrician in name, not in practice. He probably does not attend 20 cases in a year. His obstetric practice is limited to the few special cases to which he may be called in consultation and his teaching is necessarily of the book, not controlled by that wide personal experience only to be acquired by the constant observation of large numbers of cases such as falls to the surgeon, the physician, or to himself as a gynæcologist in the course of their daily work. They, however, aim at and attain a high standard of theoretical teaching and all credit is due to the men who under these very imperfect conditions have done such admirable work as teachers and investigators. In many of the provincial schools the lecturer is a *successful* general practitioner, to whom the Fates have given a large obstetric experience, but whose scientific training for this work and whose experience as a teacher may have been quite inadequate.

It is essential to have a scheme which shall place the possible to remove the growth entirely with certainty in the first instance.

Effect of Directly Exposing but not Removing Gliomata.

In 1890—that is, 16 years ago—my attention was drawn to the remarkable progress of a case of glioma of the cerebrum which was referred to me by Dr. Buzzard for operation on the understanding that the operation should not be completed if the hemiplegia should be increased or made permanent. The tumour was found at the point diagnosed but it was so large that obviously its extirpation would have been followed by some permanent paralysis. The wound was therefore closed and the patient made a good recovery. Two and a half years later the patient accidentally infected himself with erysipelas and died in another hospital. At the post-mortem examination it was found that the tumour had disappeared, leaving a cicatricial and degeneration cyst. Since then I have operated on ten cases of similar nature but not always defining the tumour itself. In all, however, classical symptoms were present—namely, double optic neuritis, headache, vomiting, and varying motor and sensory paresis, together with severe intracranial tension and bulging of the brain through the opening of the dura mater. I may quote the two most recent of these cases.

The first case was that of a boy who was admitted into University College Hospital with left hemiplegia and Jacksonian epilepsy, optic neuritis, stupor, and vomiting. At the operation I found that at least the middle third of the cerebral hemisphere, principally the leg area, was involved in a dark red diffuse growth. Regarding it as inoperable I closed the wound, hoping that the tumour would undergo retrogression in accordance with the previous cases. This duly happened, and the boy is growing and is bright and intelligent. Examined on July 10th, 1906, two and three-quarter years since the operation, he seems to be normally healthy, except that there is a considerable degree of spastic hemiparesis of the left leg and to a less degree of the arm. Occasionally he has cortical twitching of the left leg. The second of these two cases is that of a medical practitioner, whom I saw in October, 1902, with all the symptoms of a rapidly growing malignant tumour of the left lateral lobe of the cerebellum. As this was apparently confirmed when I opened the skull and dura mater by the extreme turgescence and deep-red colour of the cerebellum, I closed the wound, considering that the original intention of palliation of the headache and neuritis was the only possible treatment. His recovery was, however, so complete that in a few months he returned to his practice, which he has been carrying on ever since. Cases of this kind are clearly comparable to those which Dr. T. R. Glynn has published of subacute encephalitis and internal hydrocephalus simulating cerebral tumour. It is, however, of course, difficult to determine the parallelism between his series of cases and mine, as only in one was an operation performed, but in that instance the relief of the cerebrospinal fluid was followed by complete recovery.

I venture to think that we are justified in making the following general deductions on the question of the surgical treatment of malignant disease of the encephalon: (1) That operation should be resorted to as early as possible; (2) the tumour should be, if possible, freely exposed and examined and extirpated with surrounding tissue; and (3) that if it cannot be removed without undue interference with important or essential structures there remains some possibility of the tumour undergoing retrogression in a certain number of cases.

Conclusion.

In bringing this discussion of but one set of cases to a close some explanation is, I think, due from me why I did not follow the customary course of accumulating the records of as many cases as possible from the literature and basing my deductions on that basis. My reason is that the massing together of cases treated by different surgeons under diffe- rent conditions of operative technique with different clinical histories has always seemed to me an unscientific pro- ceeding. The errors of clinical observation are so numerous that to arrive at correct conclusions we ought to exclude variations of condition as much as possible. I have only now the very agreeable duty of rendering an acknowledgment of my sense of indebtedness to Dr. T. Grainger Stewart, the pathologist to the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, who has with indefatigable industry worked out the clinical records of the cases on which this address is based.

Address in Obstetrics

ON

THE TEACHING OF OBSTETRICS.

Delivered at the Seventy-Fourth Annual Meeting of the British Medical Association on August 21st, 1906.

By W. S. A. GRIFFITH, M.D. Cantab.,
F.R.C.P. Lond., F.R.C.S. Eng.,
ASSISTANT PHYSICIAN-ACCOUCHEUR, ST. BARTHOLOMEW'S HOSPITAL, LONDON.

Mr. President, Ladies, and Gentlemen,—May I be permitted before entering on the subject proper of this address to make a brief reference to the addresses delivered by my predecessors? They are few in number and appear to have been given only on exceptional occasions. That this should be one of those special occasions has been wisely determined by the council of the Association and they have placed on me the responsibility of endeavouring to make some adequate use of the opportunities which such an occasion affords.

The first, and in some respects one of the most interesting, of these addresses was given at the thirty-first annual meeting of the Association, held at Bristol in 1863, by Dr. J. G. Swayne, physician-accoucheur to the Bristol General Hospital and lecturer on midwifery at the Bristol Medical School. Of the many subjects discussed in that address, the obstetric use of chloroform, version in cases of obstructed labour, the treatment of placenta prævia, Cæsarean section, blood-letting and chloroform in puerperal convulsions, the nature of thrombosis and of phlegmasia dolens, and the operation of ovariotomy, almost all are still matters under discussion. As regards the obstetric use of chloroform Dr. Swayne said that although it had been used for over 15 years authors were not agreed as to the extent or the frequency with which it should be administered, and in reading his arguments for and against the use of chloroform we can see that medical men at that time had not learnt how to administer it in such a way as would insure to the patient the needful relief from suffering while interfering as little as possible with the normal action of the uterus. He concluded by saying that in normal labour especially he would not administer chloroform but would rather let well alone than interfere with the course of nature. Apparently very many practitioners of to-day agree with his views, and not having been taught the proper method of administration they allow many a patient to suffer severely during labour without affording them the relief that chloroform can give. Many of us will agree with him in his conclusions as to the treatment of placenta prævia—namely, that the method of version and extraction by the feet must after all be our main resort, being that most often suitable and, be it added, successful. The cases which are exceptional and require other methods are those in which the difficulty of dilatation of the cervix is considerable. Of the other sub- jects which he discusses, that of the operation of ovariotomy (then still in its infancy) must interest us particularly. Here are seen some of the pioneers of this operation: Spencer Wells, Baker Brown, Tyler Smith, and Clay, with the results involving a mortality in selected cases of from 50 to 30 per cent. Dr. Tyler Smith, then President of the Obstetrical Society of London, whose papers will be found in the third volume of the Transactions of that society, is quoted as having had seven recoveries out of 12 cases and that "one of the most remarkable features in these cases was, that in two of them the pedicle was tied with a silk ligature, the pedicle and ligature being cut as short as possible and dropped into the abdomen without producing any bad results."

The address in 1884 was given by Dr. G. H. Kidd of Dublin at the meeting at Belfast. The subject was Puerperal Fever, treated chiefly from the clinical point of view. While rightly exposing the fallacy of the theory of scarlet fever as a cause of puerperal fever, he refused to admit the general septicæmic theory because it did not include groups of cases which he supposed due to a specific epidemic disease. The 22 years which have elapsed since that date have brought evidence which convinces all who study the matter under favourable conditions that the cases commonly grouped under before his attendance upon labours were limited to the management of normal pregnancy, labour, and the puerperium, together with such complications as are common. Instruction of this kind could well be given by the demonstrator and would clear the ground for the lecturer on obstetrics, leaving him free to devote more time to the graver complications and more advanced work. The student also at this later stage of his career would be in an infinitely better position to appreciate the value of this advanced teaching.

Another method of instruction, and one likely to be keenly appreciated by advanced students, is the delivery of clinical lectures upon cases recently in the wards. Hitherto, owing to the absence of lying-in wards, such lectures have seldom been delivered. Amongst the many able and learned obstetricians in London who have from time to time endeavoured to raise the standard of teaching there is probably no one to whom we owe so much as to the late Dr. Matthews Duncan. He came to London to fill the vacant post of obstetric physician at St. Bartholomew's Hospital in October, 1877, and from the first devoted a large portion of his time and his great experience, and gradually his affection also, to his wards and his students. A "Scotsman of the Scots," he came to London believing that there was little of value to be found South of the Tweed. He gradually transferred his devotion from Edinburgh and Aberdeen to London and St. Bartholomew's. He would go to Scotland for his holiday but came back to London for his work. His influence at the hospital may be summed up in the statement that by his teaching and example he transformed the teaching of obstetrics and gynæcology from an almost insignificant position to one of the greatest importance. This change was soon felt, not only by his colleagues on the staff of St. Bartholomew's but by the students and junior officers who flocked to his lectures and wards to learn from his example that the practice of midwifery and gynæcology could be as noble and as full of dignity as that of the highest standards of surgery and medicine. This transformation was due not only to his learning and greatness as a teacher and to his success as a leading consultant—both of which were sufficiently recognised far beyond the limits of St. Bartholomew's and even of London itself—but also to the greatness of character which made it impossible for anyone to be brought in contact with him, either in hospital or palace, without feeling that the branch of the profession which he practised was as noble and dignified as that practised by the greatest physicians and surgeons. In this respect, as in the high standard of his teaching, his example diffused itself in every direction, and it is no injustice to other great teachers of his time to say that it raised the whole standard of teaching obstetrics and gynæcology throughout London. It is difficult to say whether he excelled most in his systematic or clinical lectures. Students who regularly attended his systematic lectures received a course of instruction which by its completeness rarely left any matter of importance—however recent a contribution or emanating from whatever country—lacking in their knowledge of the subject. Illumined with the criticism of his clear, highly-trained, logical mind, they were enabled to discriminate what was of permanent value and what they might expect to lay aside with fuller knowledge. His clinical lectures were models of what such lectures should be. No student could help keeping his attention fixed on the subject. No mass of detail was allowed to obscure the clearness of the main object of the lecture, so that every one carried away some important principle clearly impressed on his mind, while to the more advanced student in gynæcology the facts grouped round the main thesis (the importance of which was not always perceptible to the elementary student) afforded him further instruction, the value of which rose in proportion to his knowledge of the subject and his experience as a practitioner. The influence of such a man who combined the highest personal qualities with knowledge, experience, and clear judgment, not only in the ward and classroom but in every relation of life, raised the standard of the science and practice of obstetrics and gynæcology to a position which, at least in London, they had never before attained.

THE SEWAGE OF TAVISTOCK.—At a special meeting of the Tavistock (Devon) urban council held on August 15th a tender was accepted for £4544 for carrying out a sewage disposal scheme for the town.

SOME OBSERVATIONS ON THE EFFECT OF STERILE CASEOUS MATTER IN THE TREATMENT OF TUBERCULOUS DISEASE.

BY PETER PATERSON, M.B., C.M. GLASG., M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

I WISH to direct attention in this preliminary paper to a few observations which I have made on the effect produced in tuberculous lesions by the injection of some of the products of the tubercle bacillus as elaborated in the body.

It is well known that tubercle bacilli can easily be found in the walls of tuberculous abscesses but in the contents they may be so few that inoculation experiments may be necessary to demonstrate their presence. The conditions in the interior of such abscesses are apparently favourable to growth; the serum and soluble toxins pass into the circulation, producing more or less constitutional disturbance, whilst there is a stream of fresh serum, rich in nutritive substances, into the interior; the temperature is most suitable, and still not only do the bacilli not increase but actually diminish in numbers. There must, then, be some substance in the contents which is inimical to the bacilli and, as the fluids are being constantly renewed, presumably this deleterious material is in the encapsulated solids.

The conditions which exist in an abscess, as regards the relative proportion of caseous matter, cannot be produced in the body as a whole, still the possibility remained that the introduction of small quantities might exert a beneficial influence on the disease. But before such injections could be made it was necessary to destroy the living bacilli present, for though these may be so few as to escape notice with the microscope, inoculations show that even in these cases they are present. As it was requisite that the chemical constitution of the solids should be as little changed as possible it was evident that neither heat nor chemicals could be used for the purpose of sterilisation, and extreme cold, even though applied continuously for a long time, does not affect the virulence of organisms. Cold applied intermittently was found to produce the desired result. If tuberculous pus be kept in a refrigerator for five or six months, but allowing it to thaw frequently during that time, the pus will not induce tuberculosis when injected into guinea-pigs, even in large doses. Having destroyed the bacilli by this means the serum is poured off and the sediment is then washed for three days in a continuous stream of cold sterilised water to remove all soluble toxins. Sterile normal salt solution is now added to the fine white sediment till each cubic centimetre of the emulsion contains five milligrammes of solid substance and the material is then ready for use. Large numbers of animals have been injected with this suspension and in no instance has tuberculosis been produced. If a large quantity be injected into a tuberculous patient there is a well-marked reaction but a few minims can be given without any evident disturbance. If the opsonic index is to be regarded as the degree of resistance of the body against any particular organism then we have in this substance a means of raising the tuberculous index to a high level and that without any negative phase. In one of my patients this index rose from 0·5 to normal limits within 12 hours. Such a rapid rise is unusual but there is no difficulty in raising the index to what is regarded as normal and in maintaining it at that level. The technique necessary to obtain this index is so elaborate that it can only be conducted in a fully equipped laboratory and by a properly trained observer, and so long as it remains in this position it can only be employed in a limited number of cases. In using caseous matter I have found the temperature a convenient guide to the dose. If sufficient be introduced to raise the temperature from 0·5° to 1° the best results are obtained and at the same time the index keeps within normal limits. If there be no rise of temperature the index may still be high and yet little, if any, improvement be observed in the disease. I have found that from 0·1 to 0·5 cubic centimetre of emulsion given every second day is sufficient to raise both index and temperature. I begin with the smaller quantity and increase the amount at each injection till a slight reaction appears. The following teaching of obstetrics upon the same basis as the teaching of medicine and surgery. To devise such a scheme is not difficult, but to render it practicable within a reasonable time must be a matter of considerable expense and difficulty. It is in the first place essential that the clinical teaching be given in hospitals provided for the purpose, where a sufficient and continuous series of patients can be admitted, and having as at present a large extern department where the advanced students can attend patients at their own homes. Lying-in wards in a general hospital would be equally valuable if there were a sufficiently large number of beds to insure a regular series of patients in sufficient numbers. A small ward with a few beds is quite inadequate for routine teaching, although of great value for the admission of special cases. A large number of cases is less of a necessity than a continuous series, and I am convinced that it is of the greatest advantage to teachers and pupils that medical students should be taught their duties at the same time and place as monthly nurses and midwives. If taught separately the average student learns little of the many things every nurse knows well, and the nurse of a few months' training thinks she knows a great deal more than the medical man, and does not realise the wide gulf that separates her knowledge and practice from that of the properly trained medical men. Both student and nurse will in the wards have been taught together how to carry out their respective duties in the best manner with all the appliances and assistance which can be provided there, and in passing from the wards to the out-patient department they will learn how to carry out those principles in the simplest manner, and often enough with little to assist their wits and their fingers in dealing with the lesser emergencies which they will meet with.

Every clinical teacher of obstetrics should be a practitioner of obstetrics having charge of the obstetric wards and extern-maternity department, whose office as professor or lecturer would necessarily terminate with the cessation of his clinical duties. This arrangement would usually lead to the devolution of the greater part of the obstetric teaching to the younger members of the medical staff, with great advantage to them as well as to the students. They would have more time for visiting and clinical teaching in the labour and lying-in wards and to devote to the pathological work of their department which the older physician busy in practice may find it difficult to do.

Owing to the great difficulty that there is in providing the necessary funds for the maintenance and development of the existing hospitals, supported as they are by the voluntary contributions of a comparatively small proportion of the community, it seems hardly possible to expect that adequate accommodation can be provided in this manner in the near future, whether by the extension of the lying-in hospitals or provision of suitable wards in the general hospitals or by the foundation of new hospitals. All these are urgently needed and will require the expenditure of large sums of money. When we look at the splendid provision made for patients in the great public asylums and fever hospitals we shall be pardoned if we are inclined to look forward to a time when the great hospitals of the country shall be relieved from the eternal difficulty of finding the money necessary to pay for their daily maintenance and when we shall see them equipped in an equally suitable, though perhaps less expensive, manner by funds provided by the State, administered by the existing board of managers, under the general supervision of a responsible central hospital board or commission.

The practice of obstetrics consists of the practical application of the ordinary principles of surgery and medicine to special organs and to special conditions and yet, as stated in the report of the Midwifery Training Committee of the General Medical Council already alluded to, in 23 out of 37 medical schools students are allowed to attend midwifery practice before they have received even an elementary training in the principles of medicine and surgery. All obstetric physicians who have to teach know well that it is impossible to instruct such students with any enthusiasm, however willing the students may be to learn. The action of the General Medical Council in appointing this committee is a very important step in the right direction. The recommendations are in the main excellent and are now being considered by the various teaching bodies. They are—that every student be required to have conducted no less than 20 cases of labour, subject to the following conditions:—

A. Before the student is allowed to conduct the above-mentioned 20 cases of labour he should be required to have held the office of clinical medical clerk and of surgical dresser; to have attended a course of lectures in medicine, surgery, and midwifery; to have during one month given undivided attendance upon the indoor practice of a lying-in hospital or the lying-in wards of a general hospital; and to have therein attended cases of labour under the direct supervision of a medical officer of the hospital. He should further be required to produce a certificate from the authorities of the hospital showing that he is competent to undertake the conduct of ordinary cases.

B. No certificate that the student has conducted the above-mentioned 20 cases of labour should be accepted unless it is given by a member of the staff of a lying-in hospital or of the maternity charity of a general hospital.

These recommendations, when they can be rendered practicable and can be enforced, will meet some of the most important deficiencies suggested in this address. They will insure that the student has had a considerable part of his training in medicine and surgery and elementary obstetrics before the required 20 cases of labour are commenced; and that he will have had the same practical demonstrations and clinical instruction in the wards of the lying-in hospitals or in the lying-in wards of the general hospitals as he receives in his surgical and medical training.

The changes indicated in Paragraph B may be thought to inflict some hardship upon individual students, for at the present time the requisite certificate of attendance upon 20 cases of labour may be given by any registered practitioner. But it must be remembered that under the existing regulations the certificate affords no evidence that the student has received any instruction whatever and there is reason to believe that such indeed is sometimes the case.

While it is perfectly clear that there are many general practitioners able to give excellent instruction in some of the details of practical midwifery, it is equally certain that there are many others whose methods of practice, especially in the disregard of aseptic precautions, would make them dangerous teachers and would lead to the continuance of methods which tend to the perpetuation of the still high mortality from puerperal fever. The difficulty of making any selection in these circumstances would be very great and there is no satisfactory alternative but to adopt the course which is universally followed in the teaching of surgery and medicine—namely, to require that instruction be given by recognised teachers selected from the hospital staff for the purpose and that the instruction in practical midwifery necessary for qualification be given only by recognised teachers.

The regulation at present in existence which demands that the student shall attend courses of systematic lectures is also faulty, since it involves unnecessary labour to the lecturer and makes too great a call on the time and attendance of the student. This remark, indeed, applies to almost all systematic lectures as delivered at the present time, and many of us think that the time has come when the arrangements for such lectures need thorough revision. The great extent and variety of the subjects, on the one hand, and the excellence of so many of the text-books, on the other, make it desirable that the greater branches of medicine and surgery be taught in sections rather than in a continuous course of 60 or 80 lectures. In obstetrics the usual plan is to give a course of lectures extending over three months and delivered on four or five days in the week during the summer session; this course the student is expected to attend, but it is often quite impracticable to arrange a time for the lectures which shall permit anything like the whole number of the students to attend without interfering with their other duties, and unless (as is the case in the larger schools) a tutor is appointed to supplement these lectures by classes held at short intervals, a student may get little or none of the higher instruction which it is essential for him to receive. The lecturer on his part has year after year to spend a considerable portion of the time given to his lectures in teaching the anatomy and physiology of the female generative organs, both in the normal and gravid conditions, before he can begin teaching obstetrics proper—namely, the anatomy and physiology of labour, the management of pregnancy and labour, and the science and practice of the various complications that may arise.

It is a curious custom, but apparently a common one, for the lecturers on anatomy and physiology to omit from their systematic courses the female generative organs; hence the student learns but little of female pelvic anatomy and of such a highly-important subject as the physiology of menstruation until he attends lectures on obstetrics and gynæcology. Before attending his cases and acquiring some degree of practical acquaintance with the process of labour the student is not in a position to appreciate or even to understand much of what he hears in a course of systematic lectures. It would be better if the instruction he received

Metchnikoff and his colleagues have, so far as I am aware, published any further communications and one may assume that the results did not fulfil their expectations. The reader must be referred to the papers by Kraus and Prantschoff[8] upon cholera and other vibrios and their hæmotoxins, toxins, and antitoxins, as the details do not admit of a short analysis.

Whilst the various methods employed have led to the demonstration of toxic elements in fluid cholera cultures the filtrates obtained are less toxic than the unfiltered cultures and have not given satisfactory immunising results. The criterion of an active toxin is the production of a potent antitoxic serum. Judged by this standard the soluble toxins hitherto described have proved disappointing. This will be evident by reference to the immunising experiments of Metchnikoff and his co-workers. Two horses received subcutaneous injections of the filtered toxin prepared in the manner described, the initial dose being ten cubic centimetres. At the end of six months the horses were able to tolerate injections of 200 cubic centimetres. The injections were made at intervals of from 10 to 12 days and caused considerable local reaction. The serum mixed with the filtered toxin and injected into guinea-pigs subcutaneously gave the following results. After three months' treatment, and a total injection of 350 cubic centimetres of toxin, three cubic centimetres of the horse's serum neutralised one and a half lethal doses of the filtered toxin. After six months, and the injection of 950 cubic centimetres of toxin, one cubic centimetre of serum neutralised four lethal doses of toxin. The figures indicate that the immunising value of the toxin and the antitoxin was of a feeble character. The Behring-Ransom serum was likewise found to neutralise the same toxin. The serums prepared in goats by Pfeiffer by the injection of the bodies of the bacilli were of high bacteriolytic power but without demonstrable antitoxic action for the intracellular poison. The serum did not protect against the killed and toxic bodies of the bacilli. Whilst, therefore, it is recognised that a cholera serum should possess antitoxic qualities, Pfeiffer's serum did not exhibit these and Metchnikoff's, even after a prolonged period of immunisation, did not in its effects strikingly exceed the range of action of normal serum. Further, the feasibility of preparing an antitoxin for that primary poison which exists as an integral constituent of the cholera bacillus has remained a matter of dispute, and has been regarded as impracticable by many competent bacteriologists.

It was with the object of obtaining a definitive result, either in a positive or negative sense, that the following investigation was undertaken. As I have already briefly stated in a previous paper upon an antitoxic typhoid serum the experiments with the cholera endotoxin were successful.[9] The cold-grinding method adopted gave the necessary conditions for obtaining the cholera endotoxin directly from the living cell and studying its properties. Virulent cultures of the comma bacillus were employed for the purpose of the experiments. The organisms were cultivated on nutrient agar in Roux bottles. A watery emulsion of the eighteen hours' growth was made, which was then washed in a high-speed centrifuge. The separated organisms were triturated at the temperature of liquid air and the product was taken up in 1 in 1000 caustic potash. On spinning, a clear supernatant fluid representing a 10 per cent. extract of the comma bacilli was obtained and was treated very rapidly with chloroform vapour. The cell juices were in every instance sterile and were acutely toxic to experimental animals. The quantitative yield from the various grinds was remarkably constant and averaged about ten milligrammes of solid matter per cubic centimetre of the juices. This being the case it was possible to trace any parallelism that might exist between the virulence and the toxicity of the cultures—a matter of considerable theoretical and practical importance. It may be here stated that the cultures of high virulence yielded the most toxic and the cultures of low virulence the least toxic juices, whilst in those instances in which the virulence had been allowed to diminish to such an extent that, e.g., two platinum loops of a culture did not kill the guinea-pig, the toxicity of the juice suffered a corresponding drop, one-half cubic centimetre and even one cubic centimetre failing to kill, whilst one-tenth cubic centimetre from a virulent culture killed acutely. This leads me to conclude that as regards the cholera endotoxin virulence and toxicity are intimately related, inasmuch as increased virulence implies increased toxicity and *vice versâ*. This observation may explain the discrepant results obtained by different workers and in any case justifies the use I have constantly made of virulent cultures in my investigations upon this and other pathogenic organisms.

The variations in toxicity of the cholera cell juices I consider to have been largely dependent on variations in the toxic quality of the material at the time of grinding. The index for a good yield of endotoxin is the virulence of the given culture and this varies under laboratory conditions despite all precautions taken, and is liable to sudden drops. It is a source of trouble in connexion with experimental work on the cholera organism.

Toxicity of the cell juices.—From the most virulent cultures toxic extracts were obtained which on peritoneal injection killed guinea-pigs acutely in doses of $\frac{1}{10}$th and $\frac{1}{20}$th cubic centimetre, whilst $\frac{1}{30}$th cubic centimetre rendered the animals ill. The average lethal dose for guinea-pigs of 300 grammes weight was $\frac{1}{10}$th cubic centimetre (about one milligramme). The extracts from cultures of lower virulence killed in doses of 0·3 and 0·5 cubic centimetre. Where the virulence was feeble doses of 0·5 cubic centimetre and upwards were necessary to kill the animals. The endotoxin also acted subcutaneously. The effects were the same as on peritoneal injection—congestion of the intestine, hyperæmia of the organs, and hæmorrhages in the stomach. The doses killing subcutaneously were two cubic centimetres and one cubic centimetre. In the instances tested 0·5 and 0·2 cubic centimetre failed to kill. The results were not so constant as those obtained with the smaller peritoneal doses.

The endotoxin likewise killed rabbits acutely on intravenous injection. The symptoms were collapse, occurring about three-quarters of an hour after the injection, acute diarrhœa, and a rapid fall of temperature ending in death, at times within one hour. From the most virulent cultures $\frac{1}{10}$th and $\frac{1}{10}$th cubic centimetre of the cell juices killed acutely with the above symptoms. The average lethal dose ranged from 0·3 to 0·5 cubic centimetre. The filtered juices were also toxic—e.g., 0·2 and 0·5 cubic centimetre of a filtered juice proved acutely fatal. The rabbit was more tolerant to subcutaneous injections—e.g., one, two, and three cubic centimetres of the endotoxin did not kill but produced considerable local swelling and induration. The guinea-pig proved more uniformly susceptible and was therefore mainly employed in the subsequent serum tests.

The endotoxin was acutely fatal to goats on intravenous injection. A goat died within 12 hours after an injection of $\frac{1}{10}$th cubic centimetre (about one milligramme). A second goat developed persistent diarrhœa after a dose of $\frac{1}{100}$th cubic centimetre (about $\frac{1}{10}$th milligramme). In three other instances $\frac{1}{100}$th cubic centimetre rendered the animals ill, whilst $\frac{1}{50}$th and $\frac{1}{20}$th cubic centimetre produced acute diarrhœa and death. These examples indicate the potent nature of the cholera endotoxin when introduced into the blood stream of a susceptible animal, $\frac{1}{10}$th milligramme of the material inducing marked toxic effects.

In all the above experiments the freshly prepared endotoxin was injected. The juices deteriorate in toxic power on keeping and are readily modified by heat, as will be seen from the following experiment:—

Toxic Cholera Cell Juice.

Half hour at 55° C.	Half hour at 60° C.	Unheated.
Guinea-pig: 1·0 c.c. alive.	Guinea-pig: 1·0 c.c. alive.	Guinea-pig: 1·0 c.c. dead.
Guinea-pig: 0·5 c.c. alive.	Guinea-pig: 0·5 c.c. alive.	Guinea-pig: 0·5 c.c. dead.
Guinea-pig: 0·3 c.c. alive.	Guinea-pig: 0·3 c.c. alive.	Guinea-pig: 0·3 c.c. dead.

The toxicity of the cell juices in the above doses was destroyed after half an hour's heating to 55° and 60° C. The results were the same in the case of the typhoid endotoxin obtained under similar conditions. The soluble toxins obtained by Ransom and by Metchnikoff resisted heating to 100° C.

Immunising experiments.—These were carried out on the rabbit and the goat. Normal rabbit's and goat's serum had no appreciable neutralising effect on the toxins obtained is a short summary of several cases in which this treatment has been tried.

[9] Macfadyen: Proceedings of the Royal Society, March 8th, 1906; Brit. Med. Jour., April 21st, 1906.

CASE 1.—The patient was a girl, aged eight years, with old-standing hip-joint disease. The joint was ankylosed and a sinus led from the outer side of the thigh up towards the joint. The skin round the opening of the sinus was extensively and deeply ulcerated. The sinus closed and the ulcers healed with four weeks' treatment.

CASE 2.—The patient, a boy, aged nine years, had tuberculous disease of the left clavicle, the left tarsus, and the right fibula. The left foot had been amputated and the fibula destroyed for about five inches before the treatment was commenced. When the injections were started there was a long open wound over the fibula and a sinus, discharging pus, over the clavicle. These were healed within five weeks after the injections were commenced.

CASE 3.—The patient was a girl, aged 14 years, with disease of the synovial membranes of the wrist-joint which was discharging through two sinuses. After seven weeks' treatment the swelling had disappeared and the sinuses closed. The movements, though improved, are still restricted.

CASE 4.—The patient, a woman, aged 22 years, had lupus of both cheeks of 12 years' duration. The patches were covered with small superficial ulcers and the edges consisted of a zone of firm papules. These were healed after two months' treatment, though their outline still becomes red when the patient is excited.

CASE 5.—The patient was a woman, aged 35 years, with chronic pulmonary tuberculosis. Both apices were diseased and with cavity formation. Cough was troublesome, expectoration was moderate in quantity, and bacilli were numerous. With three months' injections the symptoms have greatly improved. The râles have quite disappeared from the left apex and nearly so from the right. The cough is very slight and only for a little while in the mornings. There is almost no expectoration and the bacilli have been absent for two months.

These cases, though not by any means conclusive, are at least encouraging and justify further investigation.

Glasgow.

UPON AN ANTI-CHOLERA SERUM.

By ALLAN MACFADYEN, M.D. EDIN.,
FULLERIAN PROFESSOR OF PHYSIOLOGY, ROYAL INSTITUTION.

IT is generally accepted that the symptoms of cholera Asiatica are the result of an acute intoxication with certain products of the specific agent—the comma bacillus of Koch. Further, that these symptoms are due not to a general invasion of the body by the bacillus but to an absorption of its toxins from the seat of infection—the intestine. An intoxication being the cardinal feature in the disease the character of the specific poison became naturally a subject of close investigation, and more than one attempt has been made to isolate it and to bring the treatment of cholera within the range of serum therapeutics. Little hope of success has been found to lie in the preparation and the use of a bactericidal serum. The serum therapy of cholera, if it is to meet with any success, must rest on an antitoxic basis, bearing in mind the clinical features of the disease. This also has generally been recognised by those who have endeavoured to introduce specific methods of treatment.

Numerous efforts have been made to obtain toxins from cultures of the cholera organism. Two theories, apparently contradictory, arose with regard to the nature of the specific toxins and gave rise to much controversy. It has been maintained, notably by French observers, that the poison is a genuine secretory product, both *in vita* and *in vitro*, and extracellular in the sense of being diffusible and soluble. Others, and pre-eminently German observers, maintain that the poison is inherent to the cell plasma and therefore of the intracellular type. The point of view determined in each case the method of investigation employed. The upholders of an extracellular poison endeavoured to obtain a secreted toxin by the cultivation of the bacillus on fluid laboratory soils, whilst those who held the poison to be intracellular worked with the killed and undoubtedly toxic bodies of the bacilli. It may be useful to summarise the main results that were obtained inasmuch as a good deal of the work dates ten years back.

Among the earlier observers Petri[1] grew the comma bacillus on peptone soils and obtained a heat-resistant proteid termed by him "toxo-peptone." The entire cultures, sterilised by heat, proved to be more toxic than their filtrates. Hueppe and Scholl[2] cultivated the bacilli in fresh sterile eggs. The alcoholic precipitate from the egg yielded an aqueous extract poisonous to the guinea-pig. This effect was, however, shown to be due mainly to ordinary decomposition products and the retained alcohol. Gamaleia,[3] as the result of his investigations, came to the conclusion that there are several cholera toxins. The organisms grown on a special veal broth yielded two soluble poisons—the one, thermolabile, produced diarrhœa in the rabbit, and the other, thermostable, caused an intoxication but without diarrhœa. The doses required to bring about these effects were considerable. Behring and Ransom in 1895[4] described a soluble poison obtained by them from fluid cultures of the comma bacillus which was heat-resistant and acutely toxic to the guinea-pig in concentrated doses. For this poison they were able to prepare an antitoxin. It can hardly be supposed that these observers were dealing so much with the genuine poison as with secondary products which are to be met with in old cultures of the cholera and other organisms. Nor does their serum appear to have exhibited antitoxic properties much more striking than those of the normal serum. The important researches of Metchnikoff, Roux, and Salimbeni[5] call for detailed notice, both on account of the ingenious methods employed and the results obtained. Highly virulent cultures of the comma bacillus, prepared by cultivation in collodion sacs in the peritoneal cavity of the guinea-pig, were sown on a special medium containing 2 per cent. peptone, 2 per cent. gelatin, and 1 per cent. sodic chloride. A short period of incubation was given to the cultures in order to obtain the toxin before it had undergone modification. The cultures reached their maximum toxicity on the fourth day and were then filtered. The filtrate was toxic on subcutaneous injection in doses of 0·3 cubic centimetre per 100 grammes weight of guinea-pig. This toxin, similarly to Behring and Ransom's, was not sensibly modified at boiling point but lost its activity under the action of air and light. The guinea-pig was most susceptible to the toxin, other animals, such as the rabbit, requiring larger doses. The poison acted subcutaneously and peritoneally. The effects consisted in hypothermia, peritonitis, fluid distension of the small intestine, along with hyperæmia of the abdominal organs. These results appear simple and conclusive in favour of the toxin obtained being a genuine secretion product of the bacilli. They are, however, open to another interpretation—viz., that these observers were really dealing with toxic elements of the comma bacillus which had been released by autolysis and disintegration of the cells. The death-rate of organisms, even in a young cholera culture, is rapid. Gottschlich and Weigang[6] found that in a two-days' culture of cholera at 37° C. only about 10 per cent. of the bacilli were alive and on the third day at most 1 per cent. It still remains to me doubtful if such poisons are of the same character as those developed in the body in the course of a cholera infection.

Pfeiffer is the most distinguished upholder of the doctrine that the cholera poison is contained in the protoplasm of the cell. Young broth cultures have no marked toxic effect on filtration. On the other hand, carefully killed young agar cultures produce an acute intoxication of the same nature as that produced by living cultures. This has been demonstrated by Pfeiffer, in a most careful series of experiments.[7] There can be little doubt that the primary cholera toxin is of the endocellular type, of an unstable character, and is easily converted into less toxic modifications. Its demonstration, therefore, requires a careful and conservative technique. Subsequent research has *not* substantially modified the respective standpoints indicated except in so far as Pfeiffer's conclusions have met with the widest acceptance. Since 1896 neither Behring and Ransom nor

HÆMATOGENOUS ALBUMINURIA.*

BY R. HINGSTON FOX, M.D. BRUX., M.R.C.P. LOND.,
PHYSICIAN TO THE FRIENDS' PROVIDENT INSTITUTION.

History.—Nearly 50 years passed after the connexion between albuminous urine, dropsy, and kidney disease was established by Dr. Bright in 1827, before the fact was recognised that albuminuria was found in a class of persons who were not the subjects of kidney disorder, at any rate in its usual forms. It was long before the chemical examination of the urine was made a matter of routine practice even in hospitals. This became more common during the third quarter of the nineteenth century but it was not until the ninth decade that it was considered a needful part of the examination of candidates by most insurance offices. Such keen clinicians as Gull[1] and Andrew Clark[2] in this country, Vogel[3] in Germany, and Jaccoud[4] in France, did not fail to observe these anomalous cases of albuminuria at an earlier date, but so far as appears the first clear account of them was given in Moxon's paper[5] in Guy's Hospital Reports for 1878. Dukes's observations[6] at Rugby quickly followed and many of us can remember how keenly the matter was discussed by Saundby,[7] Maguire,[8] Barnes,[9] and others during succeeding years. Pavy[10] defined the cyclic type in 1885, and the more favourable view of such cases which was finding acceptance was strongly contested by George Johnson.[11] Meanwhile Fürbringer[12] and Leube[13] in Germany, Capitan[12] in France, and Stirling[14] and Grainger Stewart[15] in this country, making observations on soldiers, cadets, children, and others, showed that a large percentage of persons accounted healthy by every other test passed albuminous urine at some time in the day. Munn[16] made similar observations on American candidates for life assurance.

It has thus come to be established that there is a form of albuminuria of common occurrence the subjects of which are generally young men or boys, although there is no reason to think that the female sex is exempt; often they are pale, wanting in vigour, and dyspeptic, and are liable to faints or headaches; they have usually excitable hearts and the arterial tension varies much under slight influences. The urine is not of continuously low specific gravity; the albumin, which consists mainly of serum albumin, is often present only at intervals, following the rise from bed and entry on the work of the day, or succeeding a meal, or coming on after muscular exertion, cold bathing, or emotional strain. In other cases its presence is continuous but the amount varies. The urinary sediment contains no tube casts or renal cells, excepting that sometimes a very few small hyaline casts may be found; crystals of oxalate of lime are often present; still more frequently there is an excess of uric acid. The albumin is also found in healthy persons—that is, in those who act in all ways as such.

Nomenclature.—This form of albuminuria has been termed "transient" (Capitan,[12] 1883; Legendre[19]; Rohlfing[12]; Flensburg[18]; cf. Petit,[21] 1875); "intermittent" (Moxon,[5] 1878; Rooke[17]; Falkenheim,[12] 1884; Bertrand[12]; Broadbent[18]; Guyon[19]; Rabagliati[22]); "of adolescents" (Moxon,[5] 1878; Dukes,[6] 1878); "physiological" (Marcacci,[21] 1878; W. Roberts,[20] 1884; Leube,[13] 1887; Weinbaum[19]; Sollmann,[19] &c.); "of the (apparently) healthy" (Fürbringer,[12] 1879; Griswold[13]; van Noorden[19]; Stirling[14]; Washburn[12]); "latent" (G. Johnson,[11] 1879; cf. Gueneau de Mussy,[21] 1674; and Rey,[21] 1876); "dietetic" or "alimentary" (Stanley Rendall,[12] 1883; Grainger Stewart[15]); "cyclic" (Pavy,[10] 1885; Merley[12]; Canfield[12]; Klemperer[12]; Ostwald[19]; Heim[19]); "functional" (Ralfe,[21] 1886; Gairdner[24]; Brandreth Symonds[19]; Armstrong[25]); "paroxysmal" and "simple persistent" (Grainger Stewart,[15] 1883); "neurotic" or "emotional" (Pessez,[12] 1888; Rem Picci[12]); "postural" or "orthostatic" (Marie[23]; Teissier,[27] 1899; Stokvis[19]); "early" (Dukes,[6] 1891); "benign" (Renard,[21] 1889); and "spurious" (Pizzini,[12] 1897). The number and variety of these designations are in accord with our ignorance hitherto of the pathology of the disorder. Many of the terms describe prominent features of some of the cases, others like "functional" are little more than a cloak for want of knowledge.

Causes.—Much stress has naturally been laid on the influence of blood pressure, altered by exercise, posture, or emotion, as a cause of the condition; yet it must be granted that the same cause produces in other persons no such effect. Moreover, the signs of an unstable neuro-vascular mechanism (Pavy[10]) are quite absent in some instances. As early as the days of Prout it was suspected that a change in the albumins of the blood apart from kidney disorder might be the cause of some forms of albuminuria. This was the opinion of Jaccoud[4] and it formed the subject of a thesis by Rendall,[12] and many inconclusive experiments were made to establish the theory. Semmola[28] worked in the same field and Bamberger[29] of Vienna in 1881 described "hæmatogenic albuminuria." These views were, however, speculative and Stokvis[19] declared in 1901 that proof of their truth as an explanation of benign albuminuria was wholly wanting. Teissier[27] thought that the kidneys might be ill developed so as to be permeable to the albumin of the blood.

Sir A. E. Wright's researches.—Sir A. E. Wright's hæmatological studies[30] have produced strong grounds for the belief that this kind of albuminuria is due to a disorder of the blood, the outstanding feature of which is lessened coagulability (diminished viscidity). The evidence for this has been already detailed in THE LANCET and may be summarised as follows. 1. In four subjects of this form of albuminuria the coagulation time of the blood averaged one minute 50 seconds. It is well known that salts of calcium increase the coagulability by promoting the formation of fibrin. By the administration of calcium lactate to these four subjects the time was reduced to an average of one minute 20 seconds. The albumin had then disappeared from their urine. 2. In four cases of albuminuria with signs of disease of the kidneys or urinary passages the average coagulation time was one minute 30 seconds and it was reduced by the administration of calcium lactate to an average of 50 seconds. The albumin was unchanged or somewhat increased in amount. 3. The functional efficacy of the kidneys was demonstrated to be unimpaired in seven of the first class of cases by the determination of the "excretory quotient," which is a measure of the power of the kidney to elaborate out of the blood a concentrated saline solution. In the four cases of the other class it was found to be lowered greatly. 4. The subjects of the form of albuminuria in question have usually been undergoing rapid bodily growth, in which there is a demand for calcium, especially for bone formation, so that a deficiency of this substance in the system is likely to occur. 5. Experience has shown that a milk diet which is rich in calcium cures the albuminuria in many cases. 6. Wright ranges this symptom with a class of other "serous hæmorrhages" dependent on transudation of serum and associated with lessened coagulability of the blood; amongst these are urticaria, chilblains, and forms of headache, œdema, and weeping eczema. It is not the rule for these disorders to occur in the same subject, so that it seems that one person is vulnerable in his skin, another in his meninges, another in his kidneys; and thus far a kidney weakness may be postulated in those who have hæmatogenous albuminuria.

Further observations.—The control of the albumin by the use of calcium lactate is the chief clinical test. It has been confirmed by other observers, although no results have yet been published so far as I know. I have used the test in 16 cases of albuminuria indiscriminately. In seven the albumin disappeared or was reduced to a small trace after the taking of the lactate. These were, I believe, all instances of hæmatogenous albuminuria. In the remaining nine the albumin persisted; in most of these cases signs of kidney disease were present, but in two or three the albumin may have been hæmatogenous, needing a longer course of the calcium salt for its removal. I give brief notes of the cases.

CASES 1, 2, and 3.—In two boys, aged 11 and 16 years respectively, and one girl, aged 13 years, a pretty dense cloud of albumin was found on boiling the forenoon urine, and there was also marked excess of uric acid as shown by Simon's test.[31] The forenoon urine some days later, after two or three doses of the lactate, was free from albumin and the uric acid was also much diminished. One of the boys had a most unstable nervous system and was liable to epileptic attacks; his albumin varied from 1 per cent. (Esbach) to *nil* under changed conditions of diet and exercise.[15] I have watched this case during several months and am fully satisfied of the control of the albumin by the directly from the cholera organism—one cubic centimetre of normal serum did not neutralise two lethal doses of the endotoxin. The rabbits received subcutaneous injections of the toxic cell juices and proved tolerant to considerable doses. One rabbit received at intervals of a week 1, 2, 3, and 5 cubic centimetres of the toxin subcutaneously. The serum was tested seven days after the last injection. The serum-toxin mixture was kept at 37° C. for half an hour before injection into the guinea-pig. The results are given in the following table:—

---

* The superior figures occurring throughout the article are references to the bibliography at the end.

Guinea-pig.	Dose.	Result.
1	2 c.c. toxin + 2 c.c. serum	Alive
2	2 c.c. " + 1 c.c. "	"
3	2 c.c. " + ½ c.c. "	"
4	1 c.c. " + 2 c.c. "	"
5	1 c.c. " + 1 c.c. "	"
6	1 c.c. " + ½ c.c. "	"
7	1 c.c. " + 2 c.c. *normal* serum	Dead
8	0·2 toxin	"

One cubic centimetre of the toxic cell juice contained five ascertained lethal doses. The treated rabbit's serum had therefore acquired distinct anti-endotoxic properties, inasmuch as 0·5 cubic centimetre neutralised ten lethal doses of the endotoxin, whilst one cubic centimetre of normal serum did not neutralise two lethal doses. Other treated rabbits gave similar results after a short period of immunisation—e.g., in two instances tested, $\frac{1}{10}$th cubic centimetre of the serum protected against three and $\frac{1}{50}$th cubic centimetre against two ascertained lethal doses of the endotoxin. The injection of the fresh toxin in a condition favouring absorption no doubt favoured the result. By means of these experiments one was able to demonstrate at the outset the production of an antibody for the cholera endotoxin. It was also evident that one was dealing with an active toxin.

The further immunising experiments were carried out on the goat and the intravenous method of injection was employed. This animal is highly susceptible to the action of the cholera endotoxin, as will be seen from the figures already given, and a careful method of dosage is necessary for successful immunisation. A goat received intravenously at intervals of a week $\frac{1}{100}$th, $\frac{1}{50}$th, $\frac{1}{10}$th, $\frac{1}{8}$th, $\frac{1}{20}$th, and $\frac{1}{5}$th cubic centimetre of toxic cell juices. The animal was ill after the first injection and the subsequent doses produced distinct reactions. The serum was tested after the sixth injection. The results are given in the accompanying table:—

Guinea-pig.	Dose.	Result.
1	2 c.c. toxin + 2 c.c. serum.	Alive.
2	2 c.c. " + 1 c.c. "	Dead.
3	2 c.c. " + ½ c.c. "	Alive.
4	1 c.c. " + 2 c.c. "	"
5	1 c.c. " + 1 c.c. "	"
6	1 c.c. " + ½ c.c. "	"

The cell juice contained four ascertained lethal doses in one cubic centimetre. The figures therefore show that one-half cubic centimetre of the serum protected against eight lethal doses of the endotoxin. It had been previously ascertained that one cubic centimetre normal goat's serum will not protect against two lethal doses of the poison, nor, as a matter of fact, was there any appreciable action in two cubic centimetres of normal serum.

A second goat was treated more deliberately and for a longer period, beginning with sublethal initial doses of the endotoxin, and tolerance was established to otherwise fatal amounts. The weekly injections made were $\frac{1}{100}$th, $\frac{1}{100}$th, $\frac{1}{50}$th, $\frac{1}{50}$th, $\frac{1}{30}$th, $\frac{1}{20}$th, $\frac{1}{30}$th, $\frac{1}{20}$th, $\frac{1}{30}$th, $\frac{1}{20}$th, $\frac{1}{15}$th, $\frac{1}{15}$th, $\frac{1}{15}$th, $\frac{1}{15}$th, $\frac{1}{12}$th, and $\frac{1}{3}$rd cubic centimetre. The animal was ill after the first injections of $\frac{1}{100}$th, $\frac{1}{50}$th, $\frac{1}{20}$th, and $\frac{1}{15}$th cubic centimetre. The total amount injected was about one cubic centimetre, or 10 milligrammes, of solid matter. The injections extended over four months, the animal at the end of that time being alive and well. In the case of this goat the neutralising power of its serum was always tested against the same amount of toxic cell juice—viz., one cubic centimetre, and containing from three to five ascertained lethal doses. The serum-toxin mixture was kept at 37° C. for half an hour before injection into the guinea-pig. The following table represents the results obtained.

Serum Tests.

Goat.	Blood sample.	Ascertained lethal doses of toxin.	Amount of serum.	Guinea-pig. Result.
After	6 injections.	3	$\frac{1}{10}$ c.c.	Alive.
"	" "	3	$\frac{1}{20}$ c.c.	"
"	" "	3	$\frac{1}{30}$ c.c.	"
"	13 "	5	$\frac{1}{10}$ c.c.	"
"	" "	5	$\frac{1}{20}$ c.c.	"
"	14 "	3	$\frac{1}{20}$ c.c.	"
"	" "	3	$\frac{1}{30}$ c.c.	"
"	" "	3	$\frac{1}{40}$ c.c.	"
"	" "	3	$\frac{1}{50}$ c.c.	"
"	" "	3	$\frac{1}{100}$ c.c.	"
"	" "	3	$\frac{1}{100}$ c.c.	"
"	15 "	3	$\frac{1}{200}$ c.c.	"
"	" "	3	$\frac{1}{200}$ c.c.	"
"	" "	3	$\frac{1}{400}$ c.c.	"
"	" "	3	$\frac{1}{300}$ c.c.	"
"	" "	3	$\frac{1}{300}$ c.c.	"
"	" "	3	$\frac{1}{300}$ c.c.	"

The figures demonstrate that marked anti-endotoxic properties had developed in the serum of the goat and had increased to the degree that $\frac{1}{300}$th cubic centimetre of the serum neutralised three ascertained lethal doses of the endotoxin, a property not possessed by one cubic centimetre of normal serum. A few tests were made with the goat's serum on the rabbit and showed that the serum likewise acted on intravenous injection. For example, $\frac{1}{50}$th cubic centimetre of the serum protected a rabbit against the intravenous injection of from three to four lethal doses of the endotoxin, and in other tests similar results were obtained.

The experiments having served their purpose have not in the meanwhile been carried further, although I have little doubt that still higher serum titrates could have been obtained. They demonstrate not only the feasibility of producing an antibody for the cholera endotoxin by the method adopted, but also the practicability of raising to a marked degree the anti-endotoxic value of the serum. It remains to add that the goat's serum likewise possessed agglutinative and bacteriolytic properties—e.g., $\frac{1}{1000}$th cubic centimetre of the serum agglutinated the cholera bacilli and $\frac{1}{1000}$th cubic centimetre gave Pfeiffer's reaction. The experiments in this direction were not carried further than was necessary to demonstrate the existence of these bodies.

CONCLUSIONS.

The experiments show:—1. That acutely toxic cell juices possessing active immunising properties can be obtained from the cholera organism by the method employed. 2. That an antibody can be produced for that primary poison which exists as an integral constituent of the cholera bacillus—a matter upon which there have been considerable dispute and difference of opinion. 3. That the anti-endotoxic power of the serum can be raised to a marked degree—a matter of equal importance. 4. That the serum in addition to its anti-endotoxic possessed agglutinative and bacteriolytic properties. 5. That in the case of the cholera organism there exists an intimate relationship between its virulence and toxicity. 6. That the cholera endotoxin obtained under the conditions described is thermolabile, being readily destroyed at 55° and 60° C.

Weymouth-street, W.

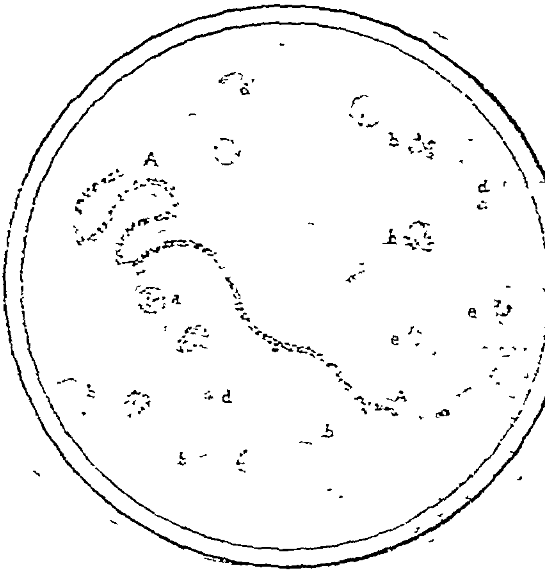
TWO CASES OF MULTIPLE INFECTION.

BY G. C. CHATTERJEE, M.B.,
ASSISTANT BACTERIOLOGIST, MEDICAL COLLEGE, CALCUTTA.

THE following is an account of two cases of multiple infection which came under my observation.

CASE 1.—The patient, a man, aged 40 years, was admitted into the Medical College Hospital, Calcutta, on Nov. 20th, 1903, for fever and jaundice. He gave a history that he had been suffering from the disease for a week. The fever was continuous and was ushered in with ague, but these symptoms ceased after admission. At the time of admission he was found to be markedly jaundiced. His intellect was dull. The pulse was slow (60 per minute). The spleen was just below the costal arch. The temperature was 102° F. on admission; it rose to 104° in the afternoon. There was no ague. Quinine was given hypodermically in the afternoon. On the next day the morning temperature was 101°. It rose to 102° in the afternoon and under repeated quinine injections the fever fluctuated between 100° and 102° for a week and then left.

Examination of the blood of the patient showed a remarkable appearance. In every field numerous malaria parasites of all shapes and sizes were found. The following is a description of these parasites. 1. Numerous crescents; from ten to 12 were present in each field. Some were still immature and intracorpuscular, others were fully developed, and some were of a spheroidal shape. 2. A great number of rings were found; they were mostly small rings with a single chromatic body. The ring was linear, the corpuscle showing a few coarse stipplings. There was no change in the corpuscles. A few free rings were also seen. 3. Half-developed parasites. There were a good many of these found. Most of them showed a big chromatic body surrounded by a body protoplasm dotted with rod-shaped pigments. The corpuscles were enlarged and showed Schüffner's dots. There were found also a few parasites in which the pigment particles were coarse. The corpuscles in which they were situated showed no change; no stippling, &c. The suspicion that they were quartan parasites was settled by the finding of a few typical quartan rosettes. 4. Fully developed parasites with rosettes. Fully developed benign tertian parasites with Schüffner's dots were the most common and prominent. A few benign tertian rosettes with from 16 to 18 divisions were also seen. Besides, as noted before, a few quartan band forming parasites and typical quartan rosettes were found. 5. While examining one of the slides stained with Leishman's stain for the above malaria parasites there was found in one field a beautifully stained filaria embryo. The sheath is distinctly seen in the figure (A).



From a preparation made from the blood of Case 1 on the first day in the daytime, stained with Leishman's stain. A, Filaria is seen with its sheath. a, Benign tertian, a fully developed one. b, Benign tertian rosette. d, Crescents. e, Quartan, early stage.

Examination of the blood at night showed a few living filaria embryoes in a hanging-drop specimen.

Blood examined on the next day (after the quinine injection) showed numerous crescents as before, very few rings, and a few half-developed benign tertian and quartan parasites; no rosettes were seen. On the third day examination showed a good many crescents, a few rings, and no benign tertian parasites. On the fourth day crescents were found in diminished numbers. No other parasites were found. On the eighth day a few crescents were found after a long examination.

CASE 2.—The patient, a Hindoo male, aged 20 years, had been suffering from fever for a month when he came under my notice on Nov. 28th, 1903. His temperature was at that time 103° F. He was markedly anæmic; no enlargement of the spleen was perceptible. Examination of the blood showed numerous malaria parasites. These on careful examination of a stained slide (Leishman stain) were found to belong to all the three varieties of malaria parasites, benign tertian, quartan, and malignant tertian. Numerous rings were found. A good number of crescents were seen mixed with bright-coloured benign tertian parasites. A few quartan and benign tertian rosettes were seen. As I lost sight of the case no further examination of the blood of the patient was made.

The above cases are noteworthy on several grounds. Cases of true double infection by animal parasites are no doubt lactate which, however, has to be continued in bi-weekly doses to prevent recurrence.

CASES 4 and 5.—The patients were two men aged 25 and 39 years respectively, in whom a thin cloud of albumin disappeared after 30 grains of the lactate. In the latter case the effect was transient and the remedy had to be repeated.

CASE 6.—A neuralgic ailing woman, 32 years of age, passed albumin in her urine, a marked cloud on boiling. After three doses of the lactate it was reduced to a trace.

CASE 7.—A thin cloud in a hypochondriacal woman, aged 50 years, entirely passed away under the remedy.

CASES 8 and 9.—The patients were two men, aged about 42 and 50 years respectively, of full habit of body, and rather florid. They were known to have passed albumin for two and three years respectively; there were no renal elements in the centrifugalised sediment. The elder of the two took alcohol freely. The albumin was unchanged after two doses of the lactate, which was not further pursued.

CASE 10.—The patient, a man aged 35 years, had albuminuria (about 0·2 Esbach) for eight years following acute nephritis. The deposit showed a few small casts and blood discs and many fragments of uric acid crystals. Two doses of calcium lactate only diminished the quantity of albumin.

CASE 11.—A man, aged 49 years, had passed copious albumin for at least 18 years. Tube casts were numerous; the general health apparently was excellent, and the patient was stout and florid. Arterial tension was high but there was no other vascular change. After several doses of lactate the albumin was apparently increased in quantity. This is an instance of the rare condition of "albuminuria of long standing with apparent health."

CASE 12.—A man, aged 54 years, had had albuminuria for at least three years; many casts were present and the arteries were thickened. The albumin was unchanged after the lactate treatment.

CASE 13.—The patient was a woman, aged 55 years, who had had albuminuria on and off for eight years with cardio-vascular changes; the urinary sediment showed one or two casts and some renal cells. After two doses of the lactate the albumin was reduced from a thin cloud to a trace.

CASE 14.—The patient was a man, aged 58 years, who was very obese. Arterial tension was high. The albumin, which presented a dense cloud on boiling, was persistent after taking the lactate.

CASE 15.—The patient was a man, aged 69 years. He appeared worn and had thickened arteries. A dense cloud of albumin was present, with renal cells. There was no change after taking the lactate. This patient died five months later from cerebral hæmorrhage.

CASE 16.—The patient, a man, aged 75 years, in fair general health, but with a cordy pulse of high tension, was known to have had albuminuria for three years. Two or three casts were found in the sediment. There was no change after two doses of the lactate. This was a case of slow senile albuminuria.

The calcium-lactate test was applied as follows. Two doses were given, in some cases more; about 15 grains in each dose, varied according to age and body weight; the patient took one at bedtime and the second two nights later and supplied a sample of the urine passed about noon on the day succeeding the second dose. The evidence given fairly proves the existence of what I have termed "hæmatogenous albuminuria";[32] that is to say, that in many cases of albuminuria the primary cause is the state of the blood. It is probable that these cases include the bulk of those hitherto described as "adolescent," "cyclic," &c. The disturbance of the neuro-vascular mechanism so often found seems to be only a contributing cause. Further observations are needed to define the limits of the condition.

Diagnosis.—In most of the cases of hæmatogenous albuminuria the conditions already noted as to age, nervous temperament, and excitable circulation are present. Headaches or faints are common. But the three chief signs are: (1) the albumin is absent or at least lessened in the night urine; (2) it disappears after taking calcium lactate; and (3) the urinary sediment (centrifugalised or deposited after 24 hours' standing) contains no casts or renal cells, but often crystals of uric acid or oxalates. Hæmatogenous albuminuria must be distinguished from the rare condition of "albuminuria of long-standing without apparent disturbance of health" described by Dr. F. Hawkins,[33] by myself,[34] and by others, and of which Case 11 is an instance. Here the albumin is nephrogenous and possibly comes from a limited lesion of one kidney (Ziemssen); epithelial casts are shed freely, the albumin is persistent at all hours, and in Case 11 was quite uncontrolled by the calcium salt. The full diagnosis of hæmatogenous albuminuria cannot be made without a microscopic examination and the use of the calcium-lactate test, but its recognition at a first interview is often possible.

Prognosis.—Many years' experience is needful to decide with certainty whether these cases eventually become the subject of progressive kidney disease. S. West,[35] writing of "albuminuria in the apparently healthy," thinks it probable that many do so. Dukes,[6] who was inclined to the same view, has abandoned it, finding that many of his former juvenile patients are now robust men. The experience of Pavy[19] and Broadbent[18] has also been favourable. Teissier's record[27] of 28 cases under observation for ten years showed no deaths and only four ephemeral recurrences of the albumin. The opinions of some German observers are emphatic. Pribram[5] states that the cases always recover even after lasting several years and that albuminuria of puberty never develops into nephritis. I have recorded in a paper read recently before the Life Assurance Medical Officers' Association the sequels of 111 consecutive cases of albuminuria found in life examinations for certain insurance offices and institutions between 1884 and 1896; 19 were more or less of the cyclic type. The result of inquiries made in the present year after the lapse of a period varying from ten to 22 years is as follows. Of the 19 cyclic cases one patient has died from tuberculosis of lungs and larynx and one from accident, and the remaining 17 are living, most of them apparently in good health. The sequel of the 92 other cases of albuminuria (including 63 of traces only) is also not unfavourable; six patients are known to have died and eight have been lost sight of; 78 are living, mostly in good health. Mr. E. R. Bickersteth of Liverpool kindly allows me to state his experience. More than 20 years ago he examined a large number of youths, aged from 15 to 16 years, for entry as junior clerks into insurance offices and banks and found albumin in the urine of more than one-quarter of the number. He dieted them, allowing no butcher's meat, and the albumin totally ceased in almost all cases. He had the opportunity of watching several of these youths for many years afterwards and found that after full maturity and the completion of growth the liability to pass albumin ceased altogether.

So far, then, the evidence suggests that we need not take a serious view of this disorder. It is indeed pathological, as chilblains and urticaria are pathological, and the term "physiological albuminuria" is a misnomer. But the prognosis is mainly that of the state of blood-debility, of which it is only a symptom. For life-insurance purposes I advise that a small extra be usually imposed, but some cases, after the urine has become free from albumin, may be taken as first-class lives.

Treatment.—Clinical instinct has not been at fault in the treatment of these cases, albeit their pathology was unknown. Rest in bed, a milk diet, saline purgation, iron, and nux vomica—tonics for the blood and nervous system—these means were used long ago and they cured the disorder. Rest may, however, be overdone, for, as Armstrong[25] has well pointed out, the school boy is all the better for his fresh air and play, though he should not compete in races. The value of milk is probably due to the calcium which it contains; and the salines produce a watery osmosis which renders the blood more concentrated. Alcohol should not be given, for it is a "lymphagogue," and is suspected of producing the disorder. The direct use of calcium lactate gives us a new and effectual means of altering the blood state on which the transudation of albumin depends. It is needful in some cases to continue its use over a long period. Nies[37] has recently studied a case in which calcium salts were not absorbed, but those of strontium and magnesium were absorbed with facility, and had a coagulative effect. Possibly Cases 8 and 9 (above) were of this kind. It would be well to try a dose (15 to 30 grains) of strontium lactate when the albuminuria is refractory to the calcium salt.

Totals	562,696 15,642	285,200 8530

Male rate = 27·9. Female rate = 29 8. 24,172 deaths on population of 847,796 = rate of 28 6 per 1000.

which gives a rate (in case of Calcutta) higher than is obtained by the conventional process but which, I contend, represents the true death-rate of a city. (See Table D, below).

TABLE D.—*Miniature Bengal Population (Calcutta) at Calcutta Rates.*

Ages (years).	Males.		Females.	
Under 5	55,955	@ 111·1 = 6,216	66,194	@ 108·9 = 6,555
5 to 10	64,432	@ 20·0 = 1,288	62,737	@ 22·3 = 1,399
10 to 15	52,663	@ 17·0 = 1,513	42,390	@ 20·9 = 1,683
15 to 20	36,455		38,151	
20 to 30	70,367	@ 18 4 = 2,402	75,454	@ 25·3 = 3,324
30 to 40	60,194		55,955	
40 to 50	41,542	@ 25·8 = 1,684	38,999	@ 27·0 = 1,716
50 to 60	23,738		24,586	
60 and upwards	19,499	@ 97·6 = 1,903	24,586	@ 128·4 = 3,156
Totals	424,745	15,006	423,052	17,833

Male rate, 35·3. Female rate, 42 1. Combined rate, 38·7 per 1000.

We may put these calculations in a graphic way. To obtain the standard rate for a city we, so to speak, transport the city population to conditions of life (liability to death) such as rule for the average of the whole country. By the suggested method we import the standard population into the city and place it under the conditions of life ruling in the city and we obtain thereby a rate which represents the effects of the particular city life on the standard population (Table D). It is contended that the Registrar-General's method does not give a correct result when worked on such an exceptional population as that of Calcutta in which not only are there twice the number of males as of females (and an enormous excess at certain age periods) but death-rates for males much lower at nearly all ages than those for females. The effect of the great excess of the male population at healthy ages in Calcutta is so marked that if the male population be equalised to the female at all ages the death-rate works out at 37·2 per 1000. Contrast even this correction with that usually adopted.

Bengal "standard" rate (rate for 1904) ... 32 45
Calcutta standard rate ... ... 28·6

$$\frac{32\ 45}{28·51}\ 1·1381 \text{ (factor for 1904)}$$

Calcutta crude death-rate .. 32·2 per 1000
32·2 × 1·1381 = 36·6 (corrected rate)

$$\text{Comparative mortality figure (1904)} \ldots \frac{36·6}{32\ 45} \times 1000 = 1127$$

To sum up; a miniature standard (Bengal) population (equal to Calcutta, viz., 847,796) with age and sex constitution as of Bengal at rates of mortality ruling in Calcutta gives a death-rate for the city of 38·7 per 1000 (see Table D), as compared with 36·6 by the usual method of correction.

Calcutta.

THE INDUCTION OF HYPNOSIS.

BY EDWIN ASH, M.B., B.S. LOND.,
SOMETIME DEMONSTRATOR OF PHYSIOLOGY AND HOUSE PHYSICIAN AT ST. MARY'S HOSPITAL, PADDINGTON, W.

THE correspondence arising from the account of my experiments published in THE LANCET a few months ago,[1] has shown me that there is a very widespread interest in the subject of hypnosis, an interest which is coupled with an extraordinary ignorance of the huge literature that deals with this condition and in some quarters expressed by a still more extraordinary scepticism as to the existence of such a mental state. The interest thus evidenced has prompted me to give some further account of my investigations during the last six months, and to show that the condition of hypnosis can be examined by anyone who takes the trouble to put himself in possession of the requisite technical knowledge and is prepared to devote time to a definite series of experiments. My own interest in the question arose some two or three years ago, and when after months of trial I had not succeeded in obtaining a condition in the least resembling hypnosis (but had caused a good deal of amusement among my friends), my position became that of the antagonistic sceptic rather than of the unprejudiced investigator. These early attempts were made on hysterical patients of a somewhat low order of intelligence and, as I now know, my methods were hopelessly crude. After a careful study of the hypnotic literature, a continuation of my experiments with healthy male subjects was rewarded by results which conclusively proved to my mind that the recorded experimental phenomena of hypnosis were genuine enough, and a description of some of these experiments formed the basis of the paper I have referred to.

It is curious that most of us should be more sceptical with regard to hypnotic experiments than to other investigations. Perhaps this is because the medical curriculum excludes all reference to the subject and because to the majority of practitioners the writings of such men as Liébeault, Bernheim, Charcot, Braid, Esdaile, Elliotson, Moll, Wetterstrand, Bramwell, Tuckey, van Eeden, and van Renterghem are absolutely unknown. An experience such as mine makes one somewhat ashamed to have ever doubted the evidence of the many workers in this field. As a matter of fact the general agreement as to phenomena observed, recorded in so many separate centres, is the most powerful argument that can be brought to bear on the individual who persists that the investigators of hypnosis have been deceived in their observations.

The popular conception of hypnosis is that of a condition in which the subject has been deprived of all freedom of mind by the "will" of the operator. Moreover, that this latter must be a person of extraordinary "will-power," with the special facility of overcoming "weaker wills" whenever he feels so inclined; the fact that his victim may be *hundreds of miles away* seems to be of little importance. This sort of pernicious rubbish is served out to the public by the day and by the week—a public that will absorb nonsense referring to "mind" or "will" even more readily than that referring to "backache" and "liver." On the other hand, those who take the trouble to examine the condition will find that success in producing hypnosis depends rather more on the wish of the subject than on the "will" of the operator—that is to say, in ordinary circumstances if a person does not *want to* be hypnotised you cannot influence him, hypnosis being a state in which by fixing the attention the mind tends to become a blank for the time being and is *consequently* peculiarly receptive to impressions from without, such as may be given by verbal suggestion. The thing is to get the subject to fix his attention and to inhibit the natural stream of thought; then it is as if you had a blank screen on which to project ideas or pictures. If the fixation of attention is great enough or the subject's natural powers of inhibition are strong enough a condition resembling sleep ensues. Thus there are two phases of hypnosis—one in which the fixation of attention is incomplete, so that the subject, although amenable to suggestion, is yet perfectly conscious of his surroundings; the other in which the inhibition of thought is so complete that he loses touch with common. These are found mostly in connexion with malaria. Golgi[1] was the first to observe a case of double infection in a Sardinian who was suffering from daily fever of different intensity. He found quartan parasites and afterwards malignant tertian parasites. Canalis[2] observed infection of benign tertian with quartan or with malignant tertian. Romaniskwy[3] observed combination of quartan with malignant tertian in three cases. Di Mattei[4] injected a tropical parasite infected patient with quartan parasites from another patient and found the tropical parasites with quartan. Vincenzi[5] observed two cases of malignant tertian with quartan. Thayer and Hewetson[6] found out of 542 malaria-infected cases 11 mixed cases, specially malignant tertian with benign tertian. Koch[7] found out of 72 cases of malaria two mixed cases (malignant tertian and quartan). Mannaberg[8] saw two cases in which the blood showed malignant tertian and benign tertian parasites. Ruge[9] described some cases of benign tertian and malignant tertian with charts. He observes that both parasites cannot remain for a long time beside one another. The small rings crowd out the large rings, and Mattei has shown by inoculation experiments that either this happens or that the big parasites crowd out of the field the malignant tertian parasites. He also observed cases of malignant tertian with quartan. He says that combination of benign tertian with quartan is possible theoretically but he has no personal experience of a case. Serg Marc[10] observed 3 per cent. of double infections in an epidemic of malaria in Turkestan.

---

[1] cet, Jan. 27th, 1906, p. 216.

Mixed infection of malignant tertian with benign tertian or quartan is not very uncommon in Calcutta. Altogether nine cases of double infection (seven benign tertian with malignant tertian, and two malignant tertian with quartan) came under my observation. Cases of combination of three varieties of malaria parasites are, however, very rare. Serg Marc[11] observed a single case but he is doubtful whether it can be called a true case of triple infection; the following is a short account of the case A patient was admitted into the military hospital at Tashkend for quartan fever on Feb. 17th, 1902. On the 18th examination of the blood showed quartan parasites only. On the 19th quartan schizonts with from six to eight divisions were found. On the 20th there were very few quartan parasites and on the 21st one quartan and a parasite which was evidently from its characters not a quartan parasite but a benign tertian parasite. On the 22nd two quartan and five benign tertian young amœboid forms and *one crescent* were found. 30 blood specimens prepared on the same day showed no more malignant tertian parasites. The blood was examined every day up to March 9th but no more malignant tertian parasites were found. Celli observed a case of triple infection but details of it cannot be found in the reference books available here; nor could I find reference to any other case of true triple infection.

Combination of three varieties of malaria parasites with filaria as observed by me in Case 1 must be very rare; and I could not find reference to a single case of a similar nature. Double infection of a single variety of malaria parasite with filaria has no doubt been observed. Selous[12] reported a case of benign tertian with filaria. Last year a case of fever was admitted in one of the hospitals in Calcutta, which was treated as a case of filariasis on account of the presence of filaria in the blood, though the blood of the patient was crammed with crescents, which were detected accidentally in examining for the filaria.

In conclusion I beg to thank Lieutenant-Colonel G. F. A. Harris, I.M.S., visiting physician, Calcutta Medical College Hospital, for kindly allowing me to publish Case 1.

Calcutta.

ON THE CORRECTION OF DEATH-RATES

BY T. FREDERICK PEARSE, M.D. BRUX.,
F.R.C.S. ENG., D.P.H. CANTAB.,
ACTING HEALTH OFFICER OF CALCUTTA.

FOR some time past I have had doubts as to the sufficienc of the Registrar-General's method for working out the so called "corrected" death-rate for a town or district. Thi "corrected" death-rate may be approximately correct whe the *numbers* at the several age *periods* are *approximatel* equal and have nearly equal death-rates, but I shal endeavour to show that the usual method will not produce correct result when there is a great difference in the number at the several age periods and at the same time there ar widely different rates of mortality. I take for my exampl the city of Calcutta, the population of which is shown i the following table (Table A.):—

TABLE A.—*Mortality of Calcutta, 1904.*

Ages (years).	Population of Calcutta, census 1901.			Deaths, 1904.			Recorded death-rates.		
	Males.	Females.	Total.	Males.	Females.	Total.	Males.	Females.	Total.
Under 5 ...	31,494	28,861	60,355	3,501	3,143	6,644	111·1	108·9	110·
5 to 10 ...	31,717	28,406	60,123	635	635	1,271	20·0	22 3	21·
10 to 20 ...	92 562	50,878	143,440	1,578	1,062	2,644	17·0	20·9	18·
20 to 40 ...	271,852	100,129	371,981	5,008	2,540	7,548	18 4	25 3	20·
40 to 60 ...	112,099	57,186	169,285	2,902	1,545	4,447	25·8	27·0	26·
60 and upwards ...	22,872	19,740	42,612	2,233	2,536	4,769	97·6	128·4	111·
Totals ...	562,596	285,200	847,796	15,858	11,465	27,323	28·1	40·1	32·

As a standard I take Bengal with a population of ove 70,000,000, a miniature of which is shown in the next tabl (Table B).

TABLE B.—*A Miniature Bengal Population (847,796) at Bengal Rates.*

Ages (years).	Males.		Females.	
Under 5	55,955 @ 101·7 = 5694		60,194 @ 87·6 = 5278	
5 to 10	64,432 @ 18·65 = 1201		62,737 @ 15 85 = 994	
10 to 15	52,563 @ 13·95 = 733		42,390 @ 12·77 = 541	
15 to 20	36,455 @ 16·74 = 610		38,151 @ 17 73 = 676	
20 to 30	70,367 @ 18·38 = 1293		75,454 @ 19 01 = 1434	
30 to 40	60,194 @ 20·67 = 1244		55,955 @ 19 46 = 1089	
40 to 50	41,542 @ 26·05 = 1032		38,999 @ 24·18 = 943	
50 to 60	23,738 @ 38 84 = 922		24,586 @ 35·33 = 868	
60 and upwards ...	19,499 @ 76·14 = 1484		24,506 @ 61·72 = 1517	
Totals	424,745	14,263	423,052	13,340

Male rate = 33·5. Female rate = 31·5. General rate = 32·5.

Calcutta in 1904 had a recorded death-rate of 32·2 while Bengal had a rate of 32·45. The "*standard*" death-rate for Calcutta is 28·6 (see Table C below) and the death-rate corrected by the usual method is 36·6.

My proposal is that a *miniature* population of the *standard* should be taken (equal in total to that of the city under correction) and that to the numbers of this miniature standard at the several age *periods* and in the two sexes the death-rates of the city under correction should be applied. By this method we obtain a hypothetical number of deaths induction of hypnosis by making the subject gaze at a bright object held about 12 inches above, and in front of, his eyes. A convenient form of hypnoscope consists of a bright disc or mirror about one inch in diameter, mounted on a dull black surface from six to eight inches in diameter. The subject is told that by gazing at the disc he will become drowsy and eventually fall asleep; his attention being fixed on the disc and then by suggestion directed to the idea of sleep which you endeavour to make dominant. Braid originally let his subjects gaze at a bright object until they became spontaneously hypnotised, but this method takes a much longer time than if combined with suggestion, and, moreover, is frequently followed by an unpleasant congestion of the patient's conjunctivæ. Having once obtained drowsiness and stiffness of the eyelids by either of the above-mentioned methods, it will be found possible with well-chosen subjects to produce subsequently the deeper stages. But at first it requires infinite patience and confidence, and a good deal of disappointment is often felt because the subjects will not fall into deep somnambulism at the mere bidding of the tyro. After considerable practice it will be found that the more adroitly the suggestions are given the more readily can the subject be led into the deeper stages of hypnosis. And whereas at first it will be found almost impossible to produce anything approaching anæsthesia, after some experiments analgesia will be produced in quite a large number of subjects; sufficient, indeed, for the painless performance of various minor operations. These points are best illustrated by an account of actual experiments. I extract the following from my notes:—

[12] *C. F. Selous*: THE LANCET, Nov. 5th, 1904, p. 1284.

A. Subject—man, aged 21 years. Had been a hairdressers' assistant. Fatigued his eyes with disc. Produced *no sleep* but slight stiffness of eyelids. Several more attempts were made to induce hypnosis by making a sudden pass in front of his face, whilst his eyes were fixed on my ring. This was eventually successful, so that half an hour from the commencement of the experiment he was in a condition of somnolence but very easily roused. I was unable to produce rigidity of the arm, nor could I obtain the phenomena of somnambulism. Again induced hypnosis and then suggested that on opening his eyes he should find himself in the last shop he had worked at. This was successful; he described a "wheel" which he said he saw in a corner of the room. I found he meant the apparatus which is used for hair-brushing. He did not see anything else but responded in part to several similar suggestions.

Up to this time the subject had apparently been in the intermediate or dream-stage as he subsequently could recollect having seen these various things as if in a dream, being aware of the fact that he was seated in my room. But he then evidently became somnambulic as he had no recollection of the succeeding incidents, which occurred as follows. 1. Having recalled the "wheel" to his mind, I told him to turn it; he went towards the imaginary machine and made movements appropriate to wheel-turning. 2. I told him to write down his name and address, which he did. He was very surprised afterwards when I showed him the paper. 3. I succeeded in producing transient catalepsy of one arm. 4. I produced analgesia, which, however, I do not think was complete. In subsequent experiments the deeper phenomena of hypnosis were readily obtained. He was very susceptible and became somnambulic in the first experiment, although care and patience were necessary to induce this stage. A beginner would be fortunate to find so good a subject for his early experiments.

B. Subject—youth, aged 13 years. Found him a difficult subject to influence, but by varying my methods I gradually induced the earlier stages of hypnosis and obtained an early phase of the dream-state. He was quite aware of his surroundings but happened to be a good visualist, so that I could successfully throw various pictures on to the mental screen.

With this subject I was unable to obtain a permanent somnambulic stage until the fifth experiment or sitting. And even then several more experiments were necessary before I could elicit the phenomena of active somnambulism. However, he eventually became deeply somnambulic and is of peculiar interest, because although he will accept readily the majority of hallucinatory suggestions, yet he maintains a definite choice of action in regard to acts that he does not approve of, or which seem to be absolutely incongruous. For example, I accidentally discovered that he was a teetotaler by offering him an imaginary glass of beer. For a long time he refused to drink it, but eventually, after persuading him that it was extremely mild and that he was doing it to please me he decided that he would drink it. He would not agree to drink anything stronger

On another occasion I told him that he was a milkman serving customers and then that he ought not to serve out white paint for milk. In return for this I was abused roundly—he said that he would not serve me with milk again as it was waste of time. He refused absolutely the suggestion that he was taking round paint. I persisted, however, and after getting several witnesses to act as imaginary customers and each to tell the subject that he was serving out paint instead of milk, he began to waver. He argued at great length that the milk was all right and in imagination drank a glass to show that this was so. He admitted that it smelt of paint and decided to take it back to his "guv'nor."

The interest of this experiment lies in the fact that the subject possesses considerable initiation if he likes to exert it. If you place him in an imaginary scene he will *rationally* act that scene, behaving with the same propriety and common sense as he would in everyday life.

These notes show how hypnosis was induced, and subsequently deepened, in two healthy young men chosen by mere chance for the purpose. They were aware of the nature of the experiments and were perfectly willing subjects.

May I repeat that by following out some plan of experiments similar to the above anyone interested in hypnosis can investigate the condition for himself. And whoever does so will see that far from being an extraordinary mastery of one will over another hypnosis is rather a simple state of distracted attention which can frequently be terminated by an effort of will on the part of the subject, but is, indeed, a condition in which suggestion has remarkable force by directing the attention to some idea which then becomes dominant for the time being. For example, a person has some pain; you tell him he has *not* but your suggestion makes no difference to his sufferings. You hypnotise him—that is, you distract his attention from his surroundings, including the pain—and he no longer suffers. By suggestion you raise in his mind the idea that his pain has entirely gone; this idea becomes dominant and eventually persistent, so that in waking he no longer has pain; the idea of *pain* has been dominated by the idea of *no pain*—they cannot be coexistent. In this way those who take the trouble to investigate the condition soon perceive what an important therapeutic agent we have ready to hand in hypnosis.

During the past few months my own experiments have been chiefly devoted to the investigation of methods of induction and of the experimental phenomena, but I have had opportunities of testing the efficacy of suggestion during hypnosis in several cases presenting various functional neuroses and have been more than satisfied with the results. Of course, there are limitations to the employment of this method. It is not applicable in the wards of a general hospital. Personally, I find the same difficulty, if not impossibility, of inducing hypnosis in a hospital ward as I did when first using hypnosis some years ago. This is undoubtedly because the patients' attention is distracted by their surroundings and the knowledge that they are for the time being an object of interest to everybody in the ward. On the other hand, I have known patients who have been refractory in the ward become readily influenced when treated in a quiet room apart from the other patients. Consequently, unless some special arrangement is made for treatment by this method its use in hospital will be productive of disappointment. Of course, in institutions where hypnosis is the rule rather than the exception these difficulties are not met with, as in Bernheim's hospital at Nancy, where he hypnotised large numbers of patients at every visit. Again, under certain conditions hypnotic analgesia would be extremely useful in minor surgery and in operations on the nose, throat, or eyes, to say nothing of dental extractions. But at present we have no certain method of rapidly inducing hypnotic anæsthesia and several sittings are necessary to obtain a satisfactory result; so that, although it certainly could be used with advantage for this purpose in private practice, it is doubtful if it will ever be used to any great extent in hospital work. The advantages of this form of anæsthesia for such operations as I have indicated are its absolute safety, that it can be prolonged indefinitely at the wish of the operator, and for operations in the mouth the jaw can be fixed open without the use of a gag. Moreover, reflex struggles can be entirely avoided by giving the necessary suggestions.

In conclusion, I trust that these brief notes will be helpful to many practitioners who are anxious to make use of hypnotic suggestion in their work or who want to investigate the condition from the purely psychological standpoint. Also, I shall be glad if they will help to place the subject of hypnosis on a more rational and satisfactory basis. In the scores of hypnotic experiments I have made I have never seen anything which would lead me to suppose the existence of any "mysterious" influence between the operator and his subject; neither have I seen any untoward results happen to my subjects. It seems such a pity that the majority of us in practice have neglected such a powerful therapeutic agent because we have not taken the trouble to understand it properly. No doubt when it is recognised that the keynote of hypnosis is an artificial distraction of "attention" and not an uncanny influence, the usefulness his surroundings and is to all intents and purposes asleep To say that one has inhibited the "supraliminal consciousness" or "objective mind" and unmasked the "subliminal consciousness" or "subjective mind" is really only another way of expressing the above process It obviously requires no particular inherent property or power to help a person to *fix his attention so as to stop his train of thought*—a process which may be to great extent mechanical and consequently will require some adroitness of method. So that anybody who has tried various methods of bringing about this desired object and has studied the best means of distracting a subject's attention from his surroundings and "fixing it," and has carefully observed the conditions that predispose to success, will be more readily able to induce hypnosis than another who tried at hazard to use a method he has read about but of which he has no technical knowledge. It stands to reason that the conditions that will readily fix one person's attention will perhaps disturb another person to such an extent that he will think faster than ever, instead of lapsing into a state of mental calm.

Let it be clearly understood then that an expert hypnotist is not a person endowed with some mysterious power, but is somebody who has taken the trouble to study carefully the psychology of his subjects, with the object of ascertaining what means are likely to succeed best in bringing about in them a state of mental rest, suiting his methods to every individual case. Psychologists define "Attention" as mental activity which 'raises certain sensations or ideas in point of intensity and completeness, with a corresponding lowering of simultaneously presented impressions—a process familiar to everybody in daily life. How many people habitually close their eyes when they wish to appreciate music fully, striving to subordinate all impressions to that of sound, the appreciation of which then rises in intensity above that of the rest. Similarly a surgeon will often fix his eyes on some distant object so as to let nothing distract attention from his tactile sense which is at that moment engaged in giving an impression of some intra abdominal disorder. *In this fixation of attention we have, I am convinced, the key to the problems of hypnosis.* The attention is fixed on some point—for example, a bright disc—and is then readily transferred to the ideas and sensations suggested by the experimenter.

Let us now examine the readiest means of so fixing a person's attention as to induce hypnosis and consider the experimental phenomena that can be demonstrated in that condition. As a matter of fact, to anybody who has not had previous experience of hypnotic experiments and is anxious to induce hypnosis the subject is at first of greater importance than the method. There are a large number of people who are readily able to "stop thinking" and to fix their attention at will. Such people are usually in the best of health, unaccustomed to worry over trifles, and do not know what it is to have disturbed sleep or difficulty in getting to sleep. They are "susceptible to hypnosis" and may be found most frequently, as one would suppose, in the healthy working male population between the ages of 15 and 30 years. The experimenter, therefore, should find such a subject and explain to him the nature of the proposed experiments. On no account begin with people in feeble health or who are "neurotic"; males being preferable to females. And having made himself familiar with the described phenomena of hypnosis he should decide which of these he wishes to obtain in the first experiment. This is where so many fail.

Hypnosis may be very roughtly divided into three stages, namely—1. A condition of drowsiness and inability to open the eyes when forbidden to do so. 2 A dream-state in which various ideas suggested appear to the subject as if in a dream or picture. In both these stages the subject is uite aware of his surroundings and that he is being made he centre of an experiment. He feels lethargic and disinclined to move and that he cannot move his eyelids or limbs when told not to do so by the operator. 3. In the third stage the attention has been so completely distracted from present surroundings that the subject has fallen into a condition of sleep. In this state he is peculiarly amenable to suggestion, will talk when spoken to, and will describe various hallucinatory scenes that are suggested to him; and may walk about and take active part in these imaginary scenes. This is what is described as *Somnambulism* and is a condition in which an infinite variety of hallucinations may be suggested—visual, auditory, and æsthetic. When complete the subject has no subsequent recollection of his hallucinations. A characteristic condition that can usually be produced in almost any stage is that of Catalepsy; if the subject's attention be directed to any limb and it is suggested that the limb is becoming stiff an extraordinary rigidity will result, of variable duration, and for the time being quite preventing any voluntary movement of the limb affected.

Now it should be obvious that it is too much to expect that the beginner in his first experiment will succeed in producing the deeper stages of hypnosis. He must be satisfied if after many attempts he succeeds in preventing the subject opening his eyes when told he cannot do so Experience shows that some really susceptible subjects are not much influenced at the first sitting. The novelty of the experiment and the unusual requests made as to behaviour tend to produce at first a state of unrest rather than of calm. However, people very soon get accustomed to the process and the deeper stages can often be obtained at the third or fourth sitting. It is best to follow out a scheme in the experiments such as the following, which was arranged by me for the benefit of practitioners who ask for instructions in the technique of hypnosis.

Instructions for inducing hypnosis.—Carry out a series of eight experiments, each of which will undoubtedly consist of several attempts to obtain certain phenomena; these should be repeated until the required result has been obtained. The experiments are: (1) to get used to the necessary details as to surroundings and technique of the process, and, further, then to attempt the production of stiffness or immobility in the subject's eyelids; (2) to induce hypnosis by a modification of Braid's method of fixed gazing; (3) production of the intermediate dream-state; (4) to obtain passive somnambulism; (5) to change this passive state into a condition of active somnambulism; (N.B., these experiments include the investigation of altered sensibility (analgesia and anæsthesia) and the production of catalepsy; (6) demonstration of post-hypnotic influence; (7) hypotaxy or fascination; and (8) hypnosis by passes Space will not permit me to enter into a detailed description of the above course of experiments, consequently I must be content with mentioning a few of the more important points. The instructions I give for the first experiment are briefly as follows.

Experiment 1.—1. Seat the patient in a comfortable armchair with his back towards the light and see that he is comfortable in every respect, especially that his head and neck are not in a strained position (this happens with so many chairs that *look comfortable*). 2. Tell him that when you say "Now" he is to close his eyes and not to analyse his sensations nor to resist the feeling of loss of contact with his surroundings that will tend to overcome him. 3. Place the thumb of the right hand on the centre of the subject's forehead, resting the fingers in the left temporal region. 4 Suddenly press firmly with the thumb, at the same time drawing it downwards towards the root of the nose. Then say, "Now close your eyes," in a quiet but very clear and firm voice. 5. Repeat the friction movement with the thumb several times rapidly (four or five movements may be sufficient). 6 Remove the hand quickly and say, "You *cannot* open your eyes, they are very stiff—firmly fixed—and you *cannot* move the lids."

Result of experiment.—1. At first the subject will probably open his eyes with very little difficulty, but you assure him that they were stiff and did not open as quickly as usual. 2. Repeat the experiment half a dozen times. 3. Above all, *be confident.* Let your subject know that it is only a *matter of time*; that very shortly he will be unable to open his eyes when you tell him he cannot. 4. With a susceptible subject you will find that the eyelids become stiffer at each attempt, then there will follow a *momentary* inability to open them, and finally, absolute closure which remains until you tell the subject he can open his eyes again. Having done this you will have got over the first stage successfully, and, what is extremely important, you will have gained a vast amount of *self-confidence.* (N.B.—1. Throughout the experiment let your manner be quiet, sure, and decided. 2. Let there be no hurry and no manifestation of impatience. 3. Should the subject open his eyes readily, be quite unperturbed, and say as firmly as before "Just once more, if you please," or words to that effect. 4. If you are losing confidence postpone the experiment to another day. 5. In any case do not prolong the first experiment over half an hour.)

Experiment 2.—The second experiment deals with the by Morat and Dastre on the sympathetic nervous system. The work is divided into two parts, Part I. dealing with elementary nervous functions, occupying a little over 100 pages, while Part II. treats of elementary systematic functions.

The first part deals with general nerve physiology, here many of the illustrations and apparatus are taken from Waller's *Physiology*. By far the most interesting section is that on systematic functions which originate in the associations and definite relationships established between the cellular functions.

The scope of the second part will be best understood by referring in broad terms to its subject matter under the head of *Sensibility and Movement: their Relations.* Under this head spinal and cranial nerves are dealt with. Following on this are what the author calls "primary systematisations," which include such subjects as reflexes, inhibition or arrest of reflexes, and classification of nerves. This leads to a study of "Consciousness and Unconsciousness," including such subjects as dispersion and reflexion of the excitations, the great sympathetic nervous system, transmission and centralisation of stimuli, and the medulla oblongata. Under the head of "Superior Systematisations" the following problems are discussed: orientation and equilibrium; the functions of the cerebellum; the emotions and intelligence; cerebral localisation; specific innervations, including the sensory field, tactile innervation, and the muscular sense; visual innervation; auditory innervation; olfactory and gustatory innervation; and, lastly, language and ideation. The author assumes the existence of the neuron as the static unit of the nervous system, but looks on this cellular unit as a *symbiosis* in the sense that to the fundamental cell, of which it consists, others are added which in a way form one structure with it. Corresponding to this unit, the author postulates a dynamic unit "by the unsatisfactory name of elementary nervous irritability." We find the word "force" used and applied as "chemical," "caloric," and "electric."

Professor Morat it will be seen treats his whole subject in a novel and original way. Proceeding from the simple arrangement of spinal nerves he gradually evolves his matter in a most interesting manner, setting it forth with all the precision and clearness that characterise the writings of a cultivated Frenchman. Numerous anatomical illustrations—many from Poirrier and Charpy and van Gehuchten—greatly aid the reader in the chapter dealing with the cranial and other nerves. A very terse and explicit account is given of the spinal and other reflexes of the cord and the sympathetic system; all these subjects are illustrated by numerous diagrams, some of them in colour. A remarkably vivid picture is that (Fig. 129) showing the effect of stimulation of the cervical sympathetic in the dog on the blood-vessels of the mucous membrane of the mouth and tongue. Better illustrations are given of the effects of removal—whole or partial—of the cerebellum than are given in English books. We refer to the results of Luciani and Thomas. In connexion with localisation in the cortex, as defined by Sherrington and Grünbaum by the unipolar method, we failed to find a sketch of the cortex cerebri showing graphically the disposition of the motor areas in the anthropoid apes. In connexion with auditory innervation the author adopts the classification of Bonnier and treats of the baræsthetic, manæsthetic, and seisæsthetic functions of this apparatus—terms which so far have not found a place in English text-books. There is a fairly complete bibliography appended to each chapter.

We welcome this translation as it introduces many new ways of looking at nervous activity in its various forms, while it may be regarded as setting forth the views of one whose name stands high both as an investigator and expositor amongst contemporary French physiologists.

Preservatives in Food and Food Examination. By JOHN C. THRESH, M.D.Vict., D.Sc. Lond., F.I.C.; and ARTHUR E. PORTER, M.D., M.A. Cantab. London: J. & A. Churchill. 1906. Pp. 484. Price 14*s*. net.

THE important question of preservatives in food has been strongly revived by the recent meat trade scandals; and owing perhaps to the same disclosures certain of the recommendations of the Departmental Committee on Food Preservatives, which was appointed in 1899 and which reported in 1901, have received official recognition, since not many weeks ago the Local Government Board issued a circular to public health authorities and others asking for their coöperation in stamping out the practice of preserving milk with antiseptics.

At first sight the book of Dr. Thresh and Dr. Porter would appear to have been written in defence of the preservative. In the preface, for example, they express the opinion that the dangers arising from the use of preservatives have been greatly exaggerated. Further on, however, they admit that certain preservatives, either from their quality or from their use in excessive quantity, have an injurious effect upon health, and that the further increase in the use of preservatives may by their cumulative action deleteriously affect certain organs or insidiously undermine the constitution. The authors therefore approach the subject in the right spirit, anxious as far as possible to elucidate the truth. As far back as 1897, in a special commission on the subject, we expressed the opinion that in certain circumstances and in certain foods a minimum quantity of a given preservative might be allowed, and that it should be the duty of the legislature to protect the public against the abuse of such a concession. The recommendations of the Departmental Committee appeared four years later and were practically in agreement with this view. They proposed the prohibition of any antiseptic whatever being added to milk, or infant and invalid foods. They suggested that a limited quantity of borax might be allowed in cream and butter or salicylic acid in wine, but ruled out the use of formaldehyde entirely as well as the addition of copper salts to peas. These recommendations made five years ago are, unfortunately, still recommendations; they are often regarded, however, as semi-official and proceedings in the police courts are accordingly based on them with the result that the most diverse decisions are given. It is not difficult to gather from their treatment of the subject that Dr. Thresh and Dr. Porter on the whole favourably regard the conclusions of this committee, and we think ourselves that the report was an excellent and able one, threatening no hardships to any man and providing means for the protection of the public against an abuse of privilege.

One aspect of the subject, we suggest, has escaped the authors. "It would certainly be strange," they write, "if with the advance of scientific knowledge better preservatives could not be discovered than those which were originally discovered by uncivilised or semi-civilised man, yet the old preservatives are permitted without question although some of them are more deleterious if taken in immoderate quantities than their more modern substitutes." The authors have surely forgotten that the fact that a ham or a haddock, for example, is preserved with smoke is patent to everybody, there can be no deception about it. None, however, but the scientific analyst can decide whether food is preserved with borax. Modern preservatives, of which the authors speak, are, in fact, "silent" in the sense that, as a rule, they possess no taste or smell which would reveal their presence. Moreover, smoke not only preserves meats but gives them also a flavour which is esteemed. Smoke and salt are thus in the same class, inasmuch as they are condiments as well as preservatives. We do not imagine that of the condition will be more thoroughly appreciated by both the profession and the public.

Duchess-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF PARAMYOCLONUS MULTIPLEX WITH FIBRILLARY TREMORS.

By A. W. Falconer, M.B., Ch.B. Aberd.,
house physician, bradford royal infirmary.

The patient, a male, aged 32 years, was admitted to Bradford Royal Infirmary under the care of Mr. T. Wilmot. The patient had not worked for about 15 months. He gave up work on account of general weakness. For about 12 months he had had violent twitchings of his muscles. They began *in the muscles of his leg* but rapidly involved the shoulder muscles. The *contractions caused no pain*. He was able to get about but could only walk slowly and with great care. He had never fallen. For the last five months he had been almost constantly in bed. Otherwise he had nothing to complain of. There was no history of fits or of any nervous disease in the family.

On admission the patient was found to be a well-nourished man. The temperature was 98·4° F. and the pulse was 80. As he lay in bed he was suddenly seized with extremely rapid muscular contractions of the muscles of all his extremities and of both platysmas. The face, with the exception of the platysmas and the *depressor anguli oris*, was not affected. In the arms the muscles most affected were the deltoid and triceps, in the back the trapezei and latissimi dorsi. Occasional twitchings were seen in the flexors of the forearms, but they were not nearly so frequent or so violent as those of the muscles of the shoulder girdle. When the patient sat up slight twitching could also be seen in the erector spinæ. In the legs the quadriceps extensors were much the most affected. The hamstrings were affected to a much less extent. Contractions could also be seen occasionally in the tibiales antici. In both quadriceps extensors fine, fast, *fibrillary tremors could be* frequently seen though they were not constant. The same tremors, though to a less extent, could be seen in both deltoids. The contractions were extremely rapid, quite painless, and generally symmetrical, though at times, especially the contractions of the muscles of the forearm and leg, were limited to one side. The right platysma was more affected than the left and here frequently numerous contractions followed one another and seemed to end in a short tonic contraction. Voluntary movement for a time inhibited the contractions, but in a few seconds they began again—e.g., the patient could touch his nose with his forefinger accurately, but if he continued to do so the movements commenced again and soon became more violent than before. The patient's gait was normal though slow. While walking the movements of the legs ceased but those of the trunk continued. Romberg's sign was negative. The movements quite ceased in sleep. There were no paralysis, no *rigidity*, and no wasting of any of the muscles. The superficial and organic reflexes were normal. The knee-jerks were markedly exaggerated. There was no ankle or rectus clonus. Sensation was absolutely normal. There was increased motor and electrical excitability of the quadriceps extensors and the deltoids, otherwise the electrical reactions were normal. The *cranial nerves* were quite normal; there was no nystagmus. The fundi oculorum were normal; the mental condition was quite normal; the heart, the lungs, &c., were also normal. The patient was treated with galvanism to the spine and a mixture containing belladonna and arsenic. On June 26th the movements were as before but he had become somewhat excited. His pupils were moderately dilated and very sluggish to light. He had also developed an erythematous rash on his back. He was taken off the belladonna and put on bromide. On July 2nd the pupils reacted; the movements were as before. His mental condition was normal. On the 5th the patient went out at his own desire *in statu quo*.

I am indebted to Mr. Wilmot, medical officer to the Bradford Royal Infirmary, for permission to publish this case.

Bradford.

NOTE ON A CASE OF UPWARD AND BACKWARD DISLOCATION OF THE CLAVICLE.

By L. Ernest Acomb, M.R.C.S. Eng., L.R.C.P. Lond.,
house surgeon to the middlesex hospital, london, w.

The patient, a spare, well-grown man, 55 years of age, whilst crossing the road was knocked down by a hansom cab. He remembered being struck on the head and was assisted to his feet in a dazed condition and accompanied to his home by a friend. He sustained a scalp wound which bled profusely, but was unaware of any injury to his shoulder until the following morning, when he found that his left shoulder was painful, and in order to relieve the pain somewhat he had to support his elbow. He was able to raise his arm slightly, but this movement caused great pain.

On examination the left shoulder drooped forward and there was a depression in place of the prominence caused by the forward convexity of the clavicle. The articular facet of the acromial process could be *distinctly felt*, while the acromial end of the clavicle *projected* backwards under the skin covering the suprascapular fossa. The distance from the acromial end of the clavicle to the coracoid process measured on the left side four inches and that on the right side three inches. There were some swelling and bruising of the part. The sternal articulation of the clavicle appeared to be in no way affected. Reduction without a general anæsthetic was found to be impossible, the acromial end of the clavicle being apparently entangled amongst fibres of the trapezius. Under chloroform reduction was effected, but the bone could not be retained in the proper *position*.

The patient was admitted into Middlesex Hospital on April 27th, 1906, under the care of Mr. A. Pearce Gould, who, on April 30th, wired the outer end of the bone into position. Mr. Gould made a curved incision so as to enclose the projecting outer end of the clavicle within the concavity of the incision. The end of the bone was found to have separated the fibres of the trapezius and to have become entangled within them. *The bone* was disentangled and holes were bored in the acromion process and the outer end of the clavicle respectively; a soft wire was then passed through, *twisted* tightly, and the ends cut short were battened down. The patient made an uninterrupted recovery and when discharged on May 17th could use the arm well, the movements daily improving. When he returned from the convalescent home three weeks later he could raise his arm as high above his head as on the uninjured side.

The most usual dislocation of the clavicle is at its outer end, with the acromial facet resting on the upper surface of the acromion process. In this case the outer end of the clavicle had passed much further back across the whole length of the acromion and was resting on the spine of the scapula. The whole of the coraco-clavicular ligaments must have been torn across. *I cannot find* a similar degree of displacement recorded by any of the surgical authors to whose works I have access.

I am much indebted to Mr. Gould for allowing me to publish this case and for his help in these notes.

Reviews and Notices of Books.

Physiology of the Nervous System. By J. P. Morat (Lyons). Translated and edited by H. W. Syers, M.A., M.D. Cantab. With 263 illustrations (66 in colours). London: Archibald Constable and Co., Limited. 1906. Pp. 680. Price 31*s.* 6*d.*

The French treatise on physiology by Professor Morat and Professor Doyon is well known to all physiologists in its native garb. The translator has selected the volume dealing with the nervous system and perhaps wisely, for Professor Morat's name first became well known to English physiologists more than two decades ago by the joint work done system the Latin anatomical nomenclature adopted by the Congress held at Basle in 1895 for the purpose of considering the use of Latin in the medical terminology of German-speaking countries. Each page is divided into four columns, the first of which contains the Latin text, while the other three show the corresponding terms in French, English, and Esperanto. The English portion is by no means free from typographical errors or inelegancies. For instance, on p. 1 the nasal spine of the frontal bone appears as the "nanal spine," on p. 3 the word "line" is divided as if it were a dissyllable, and the carotid groove of the sphenoid bone is given as the "carotic groove"; on p. 4 the word "face" is divided like a dissyllable; and on p. 7 the semilunar bone of the carpus is given as the "lunar bone." Again, the radial nerve of the English anatomists is a sensory nerve in the forearm, but the *nerf radial* of French anatomists includes the upper sensory-motor portion of the same nerve. These, however, are minor blemishes in a meritorious production, and are not likely to embarrass English readers.

Lectures on Midwifery for Midwives. By A. B. CALDER, M.B., M.R.C.S., Lecturer on Midwifery to the London County Council and to St. Mary's Midwifery Training School, Fulham. With 153 Illustrations. London: Baillière, Tindall, and Cox. 1906. Demy 8vo. Pp. xii.-274. Price 5*s.* net.—In response to the request of some of his pupils the author has published his lectures on Midwifery for Midwives "just in the words they were delivered to the class." The result is this little book, which contains all that is required to be known by an aspirant for a certificate of the Central Midwives Board. It is a difficult matter to write a book of this kind but Dr. Calder has certainly succeeded exceptionally well and we are not surprised that his pupils should have desired to have such excellent lectures in a permanent form. The author has carefully avoided going into too much detail but has left out nothing of importance. The chapters which we think most admirable are those on infant feeding and asepsis. The difficult subjects of the modification of cow's milk and bottle feeding are very clearly described and the reasons given for the various steps recommended. With the author's remarks on the various patent foods on the market we entirely agree: as he rightly says, "the delusive attractions of most patent foods are the simplicity of their preparation, and their digestibility, and therein lie their dangers; for the enthusiastic mother, when she uses them, usually feeds her child on too concentrated food and in too large quantities; as she discerns the expanding ability of the babe to imbibe them, and the physical results as exhibited in pounds avoirdupois." The rules laid down by the author for the prevention of septic infection (which he summarises in the form of a table) are especially good and would well bear inclusion in many text-books intended for the use of medical students. As he truly says, the midwife should ever remember "to regard the period of labour as the time the patient is undergoing an operation, when wounds are being made which have to be kept aseptic, and the puerperium as the time when these wounds are repaired by being kept surgically clean." On the whole it is one of the best books of its kind which we have read. It is a pity that the illustrations are crowded together on separate sheets and are unworthy of the excellent letterpress.

Heath's Manual of Minor Surgery and Bandaging for the Use of House Surgeons, Dressers, and Junior Practitioners. Thirteenth edition. Revised by BILTON POLLARD, F.R.C.S. Eng., Surgeon to University College Hospital and Teacher of Operative Surgery in University College, London; Member of the Court of Examiners of the Royal College of Surgeons. London: J. and A. Churchill. 1906. Pp. 409. Price 6*s.* net.—What can be said about a book which has reached the thirteenth edition? It must have supplied a want and it must be appreciated by its readers. The only essential for the continuance of a popularity such as this is that the book should be kept fully abreast of the times. Mr. Pollard has in the present edition, as in the one immediately preceding it, brought the work fully up to date without destroying its original characteristics. It will prove as useful as ever for dressers and house surgeons, and many a young practitioner will find the hints given in this book of immense value in his daily work.

Baby: Useful Hints for Busy Mothers. By EDITH L. MAYNARD, Certificated, London Obstetrical Society; late Sanitary Inspector, Sheffield. With an Introductory Note by JOHN ROBERTSON, M.D., B.Sc. Edin., Medical Officer of Health of Birmingham. Bristol: John Wright and Co. 1906. Pp. 31. Price 1*d.*—The ignorance which exists even amongst better-class mothers on the feeding and upbringing of a baby is a most extraordinary thing. The dangerous habits of the lower-class mother in regard to the feeding of her babies are well known, and we are often tempted to wonder whether the ignorance is not sometimes assumed and in reality is merely a cloak for criminal neglect. It is needful, however, not to pass too harsh a judgment on the parents of the unhappy children who suffer so terribly from the ignorance, whether it be assumed or real, of their mothers. In this little pamphlet the author has tried to give a short and trustworthy description of the right way to feed and to rear an infant. It is an endeavour to teach those mothers who, through no fault of their own, adopt methods quite dangerous to the babies for whom they are anxious to do right. It is the unfortunate bottle-fed babies who die and, as Dr. Robertson points out in his preface, in his own district during the summer, over 20 times more bottle-fed babies die than breast-fed ones, from an equal number of babies in each group. Miss Maynard has succeeded in describing in clear and simple language all that a young mother should know about the care and feeding of her baby. The directions are so good and easy to follow that no one should have any difficulty in understanding them and a perusal of this little pamphlet would do much to save the lives of many improperly fed babies. It is just the kind of book to place in the hands of district nurses and midwives for distribution amongst their patients.

A Manual of Veterinary Therapeutics and Pharmacology. Second edition. By E. W. HOARE, F.R.C.V.S. London: Baillière, Tindall, and Cox. Pp. 772. Price 15*s.*—The work has been re-written, and no one comparing it with the first edition could possibly recognise it as an extension of the same work. The first edition, if we recollect aright, was arranged on identically similar lines with a Pharmacology and Therapeutics written for human medical students by Dr. J. Mitchell Bruce; in fact, the two when placed side by side, except for the posology, appeared to emanate from the same pen, so much were they alike in their columns and paragraphs. The present work is modified both in its wording and its arrangement in every direction. The subjects of materia medica and pharmacological action, as far as the specific details of the preparation of the drugs are concerned, have been rather scantily treated, and we fear this will be detrimental to the book from the student's point of view, but it is the veterinary practitioner who will really appreciate the work. The author writes as a practitioner, and if he is superficial when dealing with pharmacological actions he is none the less thorough in his applied therapeutics. The chapters on the care and management of sick animals and on the treatment of numerous diseases are complete from the practical standpoint, and in the appendix are many formulæ and prescriptions that will prove of greatest service to veterinary surgeons.

everybody would hold that borax and salicylic acid are in any sense condiments. Vinegar, again, is an old-fashioned preservative, but what would pickles be without it or with borax added instead? The fact, too, that "modern preservatives" are more potent than the old-fashioned antiseptics constitutes a source of danger. We cannot think that the argument in favour of the use of "modern preservatives" is helped a tittle by stigmatising smoke, salt, vinegar, and so on as preservatives the harmlessness of which may be open to doubt because "they were originally discovered by uncivilised or semi-civilised man."

Dr. Thresh and Dr. Porter's book will be valued also by readers for its excellent chapters on the methods and substances commonly used in the preservation and colouring of foods as well as for the sound directions given for the detection of such preservatives. It is almost needless to add, when the wide experience which both authors have had in dealing with epidemics arising from the consumption of unsound food is recognised, that the chapters on such subjects as ptomaine poisoning, public abattoirs, contaminated shell-fish, watercress, and so on, are full of points of the greatest interest to all those concerned in the protection of the public health. There is, in fact, no more important branch of the public health service than that with which this volume deals, and the subjects are approached from a completely modern point of view.

The Operative Treatment of Fractures. By W. ARBUTHNOT LANE, M.S. Lond., F.R.C.S. Eng., Surgeon to Guy's Hospital, and Senior Surgeon to the Hospital for Sick Children, Great Ormond-street. London: The Medical Publishing Company, Limited. 1905. Pp. 144. Price 7*s.* 6*d.*

No surgeon will deny that some cases do occur in which a fracture has permanently impaired the utility of a limb, even though the broken bone has firmly united, but there will certainly be differences of opinion as to the proportion of cases in which the ultimate result of the ordinary treatment of a fracture is unsatisfactory. Mr. Lane holds that the proportion is large, while most surgeons believe that the percentage of cases is very small. Probably the truth lies between these extremes. It is, however, certain that the introduction of the x rays into surgery has somewhat shaken the complacency with which we were wont to regard the result of the splint treatment of fractures, for skiagrams show us that malplacements are by no means rare. Mr. Lane is strongly in favour of wiring or screwing the bones in all cases likely to prove unsatisfactory, so as to insure an accurate apposition of the fragments. The advantages of the operative method are obvious but its disadvantages, or possible disadvantages, are equally clear. To wire or to screw a simple fracture is to convert it into a compound fracture and the possible septic results of such a conversion include some which are very serious, but the author claims that "if due care be taken and reasonable skill be exercised the risk is practically *nil.*" We doubt if most surgeons will subscribe to this opinion. It is, however, certain that with great care the risk is very small and in some cases it is well worth while to run this risk in order to obtain the benefits of wiring and this work gives a useful account of the methods employed.

The book is printed in a very large type, technically known as "great primer," and in demy quarto size, having only some 200 words on each page. Such type is pleasant to read and forms a marked contrast to the small type so widely used nowadays, but we think that the quarto size is a little unwieldy. It is a pity that no index has been provided.

LIBRARY TABLE.

Guide to Promotion for Non commissioned Officers and Men of the Royal Army Medical Corps, with Appendix on Hints for Young N.C.O.'s on Clerical and Other Duties in Military Hospital. Compiled by Captain S. T. BEGGS M.B. R.U.I., R.A.M.C. (Militia). London: Gale and Polden Pp. 303. Price 3*s.* 6*d.* net.—Captain Beggs hopes tha this guide will fulfil a useful purpose in the corps an induce men to study for promotion. The special feature of the little book are (1) the concise form in which th information is put by questions and answers; (2) the illus trations of surgical instruments and appliances; and (3) th assistance which it is hoped will be derived from th "Appendix" in supplying a guide to young non-commissioned officers, recently promoted, who may have had n experience in routine clerical duties prior to promotion. In preparing the appendix, in the compilation of which the author acknowledges a debt to Sergeant-Major J. Tewkesbury, R.A.M.C., the following points are considered: How to take over charge of a military hospital, the clerical duties carried out by a non-commissioned officer, and th many questions which concern official papers and returns in a military hospital. The body of the book is divided into two parts and addenda. Part I. deals with infantry squad drill, stretcher drill, discipline, duties in barracks on guard and piquet, duties in camp and on the line of march, the duties of ward-orderlies and of wardmaster, the mode of carrying wounded men off the field, the immediate treatment of cases of emergency, the method of regulating the ventilation of wards, and with surgical instruments and appliances. Part II. contains additional information necessary for promotion to sergeant; it deals with transport duties and company drill (the subject-matter of these chapters being supplied by Messrs. Gale and Polden), hand-seat drill, ambulance-wagon drill, the additional duties of wardmaster, and the duties of a steward. In the addenda lists of instruments required for emergency and other important operations are given, as well as a list of the medical and surgical equipment for regimental units. From this *précis* of the contents the scope of this useful work will be seen, and it should be added that the information is given in a straightforward way. The illustrations are supplied from the blocks used by Messrs. Evans and Wormall in illustrating their catalogue of surgical instruments.

A Text-book of Botany. Part I. The Anatomy of Flowering Plants. By M. YATES. London: Whittaker and Co. 1906. Pp. 147. Price 2*s.* 6*d.* net.—This little book has been written primarily to meet the requirements of the author's own pupils in preparing for examination. It will, however, be found useful to anyone who wishes to obtain a practical acquaintance with botany without the aid of oral teaching. The book is of a suitable size for the pocket and is divided into chapters, each dealing with some particular part of a flowering plant. The derivation of the terms used is given and in nearly every case a little sketch (413 in all) helps to make the definitions clear. The arrangement of the chapters is a useful one for reference, and if the book is used as it is intended to be used—namely, to supplement practical work—we can find no fault with it. The danger of such books being used for cramming purposes should not, however, be lost sight of. The list of questions set by various examination syndicates which is given at the end of the book adds to its usefulness, but is suggestive in the direction just indicated.

Nomenclature Anatomique en Quatre Langues. (An Anatomical Vocabulary in Four Languages.) By Dr. PAUL RODET. Paris: Masson et Cie. 1906. Pp. 76. Price 1 franc 50 centimes.—In this well-arranged and useful little book Dr. Rodet has collected the Latin, French, and English equivalents of upwards of 2200 anatomical terms, and English readers of French medical literature will find it excellent for reference when an unfamiliar word of this class presents itself. He has taken as the basis of his

THE LANCET.

LONDON: SATURDAY, AUGUST 25, 1906.

The Meeting of the British Medical Association at Toronto.

IN 1897 the British Medical Association for the first time crossed the sea to hold its annual meeting in Canada, and now, after the lapse of nine years, it is paying a second visit to the same prosperous and important colony. In all parts of the British Empire the year 1897 was rendered memorable by the celebration of Queen VICTORIA'S Diamond Jubilee, and Canada in entertaining two of the best known British scientific associations during that summer did much to promote the feeling of imperial sympathy already evoked. For while Montreal gave a most cordial reception to the British Medical Association, Toronto no less hospitably entertained the British Association for the Advancement of Science. The British Medical Association is now the guest of Toronto, and the kind of reciprocity witnessed in such meetings affords the best possible illustration of the fellow-feeling which exists between the self-governing colonies and the mother country. Medical men cannot, as a rule, allow themselves long holidays, but the prospect of meeting their Canadian brethren, and of seeing something of the country upon which such lofty expectations are now set, has had such attractions that a journey of several thousand miles out and home has been cheerfully undertaken by many fortunate members of our profession.

English visitors are always welcome in Canada and sight-seers, who will find much to interest them, will travel under the pleasantest possible conditions. The climate is one of the healthiest in the world, the language is our own, social usages are quite similar, and money goes a long way, while for the lover of fine scenery there are natural marvels unapproached in the world for splendour and variety. The traveller in Canada will find an immense diversity of mountain and valley, river and lake, forest and prairie, uninhabited wilderness and fertile expanses covered with wheat. The vast chain of lakes with an area of 150,000 square miles, the northern primeval forests, the western Rocky Mountains, Niagara Falls, the Thousand Islands—some of all these at least he will see, and will understand why the Canadian loves his country, and why thoughtful inhabitants of the mother country see in Canadian prosperity such vast promises. The wheat-growing belts of Manitoba and the North-West, which make of Canada the granary of the empire, cover some 80,000 square miles intersected by navigable rivers, and the millions of bushels of grain produced stagger the imagination with their immensity. These are the sights which unroll themselves before the traveller's eye, while he proudly remembers that he has a birth heritage in their glories. For not less important to us than the commodities with which Canada supplies us is the fact that in her we have a vigorous and attached descendant, capable of assisting the motherland in various ways. We have spoken of food only, but the Canadians can turn the ploughshare into the sword and take their place in the battlefield if occasion requires, as the services of the Canadian contingents in the hard-fought fields of the South African war well prove.

Canada in the course of its material progress has been throughout served well medically. The Dominion is well provided with medical schools and there are fine hospitals in the larger towns. For the population of five and a half millions distributed very unequally over the vast area of the Dominion there are medical schools in four provinces, while there is every sign that medical development will follow quickly and proportionately upon the great rise in population now justly anticipated. In the province of Quebec there are four medical schools—comprising Laval University, in the city of Quebec; and Laval University, McGill University, and Bishop's College in Montreal. The medical schools in Toronto were fully described in a series of articles which was commenced in our issue of July 28th, p. 268, and concluded last week, but there are also medical faculties of Dalhousie University at Halifax, Nova Scotia, and of the University of Manitoba at Winnipeg, Manitoba. The oldest of the Canadian medical schools is the medical faculty of McGill University, dating from about 1830, but the University of Toronto has the largest number of medical students. All these educational bodies have the power of granting degrees and all are connected with universities either directly or by affiliation. A considerable proportion of the professors and teachers are men of unquestioned eminence, the courses of study are similar to those in Great Britain with some predominance of laboratory work over formal lectures, and the standard of the examinations for graduation is high; but, nevertheless, the curious anomaly exists that Canadian degrees are not registrable in Great Britain. This state of affairs is due to the fact that in Canada there is no Dominion examining board, but each individual province has its own system of medical registration as well as the legal control of such medical schools as may be in it, an arrangement which is incompatible with the decision of the British General Medical Council not to register colonial qualifications unless granted by universities situated in autonomous provinces. A solution of this difficulty would be a triumph of medical politics and the situation will, we hope, be debated during the meeting whose sittings will have commenced before these pages reach our readers.

The British Medical Association: The Address in Medicine.

SIR JAMES BARR chose a most admirable subject for his Address in Medicine at the meeting of the British Medical Association at Toronto, when he decided to discuss the Circulation viewed from the Periphery. Whether looked at from a physiological, from a pathological, or from a clinical point of view the interest in this theme must be of the first importance, for many theoretical and experimental deductions owe their application in the actual treatment of

JOURNALS AND MAGAZINES.

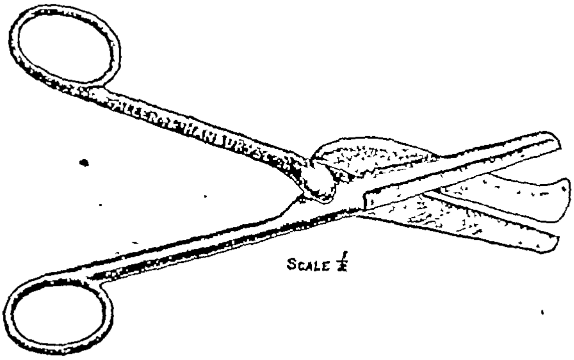
Ophthalmology. Edited, with the aid of a staff, by H. V. WÜRDEMANN, M.D., of Milwaukee. Vol. II., No. 4. July, 1906. Issued quarterly. Price 6*s.* per number or £1 1*s.* per annum. Editorial Office, 105, Grand-avenue, Milwaukee, Wisconsin, and to be obtained from George Keener and Co., 16A, Red Lion-square, London.—The original articles contained in this number are: 1. Ocular Injuries from Glass and Stone, by William H. Sweet, M.D., of Philadelphia. The author shows that notwithstanding the difficulty of obtaining a shadowing of a particle of glass or stone and localising it by means of the Roentgen rays, it may with care be successfully accomplished, and skiagraphs of small fragments of various particles are given as well as drawings showing the relations of the orbital bones to the globe of the eye. 2. Some Observations on Worth's Methods of Treatment of Convergent Squint in Young Children, by Linn Emerson, M.D., of Orange, New Jersey. The author deals exclusively with concomitant-convergent squints, which he regards as due to deficiency or absence of the fusion sense. The principles of treatment he adopts are optical correction; occlusion of the fixing eye; the use of atropine in the fixing eye; training of the fusion sense; and finally operation. 3. A Cure of Convergent Strabismus by Orthoptic Treatment at 20 years of Age, by H. V. Würdemann, M.D. 4. A Secure Looped Single-stitched Advancement Suture with a Consideration of Scleral Anchorage, by Mark D. Stevenson, M.D., of Akron, Ohio. 5. Antipyrin Keratitis, by Professor Dr. Mitsiyasu Inouye, of Tokio, Japan. 6. The Effects of "Full" and "Minimum" Doses of Atropine Sulphate and of Homatropine Hydrobromate, by Lucien Howe, M.D., of Buffalo. To determine the refraction as accurately as is possible at a single visit the author recommends a disc containing $\frac{1}{500}$th or $\frac{1}{150}$th of a grain of atropine sulphate; to learn the condition of the acommodation a disc of $\frac{1}{5000}$th of a grain may be used; to know the refraction without regard to the accommodation about $\frac{1}{50}$th of a grain of homatropine is by far the most convenient. 7. Ophthalmic Subjects in Talmudic Literature by Aaron Brav, M.D.; this is an interesting account of old Jewish terms. 8. Monocular Visible Spasm of the Central Artery of the Retina, with a case, by D. F. Harbridge, M.D., of Philadelphia. The number contains many abstracts from foreign literature, also some reviews and the index of the second volume.

Le Liège. July, 1906. No. 1. *Paris*: 52, Rue Saint-Georges. Price 2 francs.—We have received for notice a copy of this new journal which is edited by Mr. Max Hilbig. The title of the journal is printed on a very thin slab of cork adhering to the paper cover. The journal contains an interesting account of the cork-oak forests of Algeria with illustrations. The advantages of cork bricks and tiles for building purposes is pointed out and it is stated that cork is so resistant that it is not attacked by the bacterium which, under the name of bacillus amylobacter, plays such an important part in the decomposition of vegetable matters. The best corks for bottles, it is stated, are always hand-cut. It is estimated that from 25 to 27 millions of francs' worth of cork are annually transformed into corks for bottles in the whole world. The corking of bottles of all kinds is a matter of importance to the medical profession and we welcome a technical journal devoted to the interests of cork.

New Inventions.

A "SCISSORS SHIELD" FOR CIRCUMCISION.

I VENTURE to bring to the notice of the profession a little instrument for performing the operation of circumcision on very young children, no anæsthetic or ligatures being required. It is, as represented in the accompanying illustration, composed of half the ordinary shield so commonly used, the place of the remaining half being taken by the right blade of the scissors. The whole can be taken to pieces for the purpose of cleansing. I am of the opinion that by its use uniformity of results can be attained. The following are the directions for operating with the "scissors shield," which name exactly describes the instrument:—



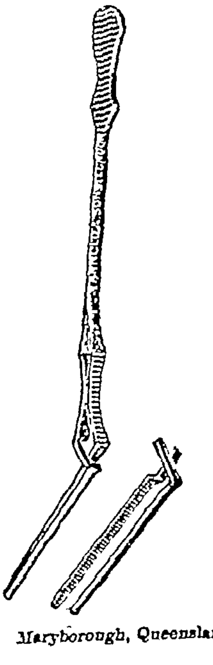
1. The prepuce to the required length is seized by the thumb and forefinger of the left hand and passed obliquely (the blades being separated) through the groove in the scissors shield, the cutting blade being above. 2. The prepuce is now cut off with one movement directed obliquely from below upwards, to avoid the vessels of the frænum. 3. The mucous lining which is now exposed over the glans is treated in a similar manner. 4. The mucous membrane is now further torn in the middle line by the fingers or cut with a scissor right down into the neck of the glans, this being the most important step of the operation. The remains of the mucous membrane is now reflected flatly and evenly downwards and held in position by a narrow slip of lint and "heft band" plaster—i.e., a piece of plaster shaped like an obtuse-angled splint. 5. In very young children anæsthetics or ligatures are not required; of course, this does not apply to older children and adults.

The instrument has been made for me by Messrs. Allen and Hanburys, also by Messrs. Krohne and Seseman.

HENRY DUTCH, M.D. Brux., M.R.C.S. Eng.

Berkeley-street, W.

A UTERINE COTTON-WOOL FORCEPS.



ALL medical men when trying to remove soiled cotton-wool from any of the different varieties of uterine probes must have noticed the difficulty which they have in doing so. For some considerable time I have been using the instrument here illustrated and have found that it easily overcomes that difficulty. I call it a uterine cotton-wool holder or forceps. By pressing the neck of the instrument the blades are separated and a piece of cotton-wool, say, two and a half inches long by two inches broad is placed between them. Then the wool is wound round the blades. To remove the soiled wool separate the blades two or three times by pressing the neck. Then take a piece of clean wool between the first finger and thumb of the left hand and push off the soiled wool. If there is any difficulty in doing so separate the blades again a few times. Messrs. Arnold and Sons of London made the instrument for me.

J. CRAWFORD ROBERTSON, M.D., C.M. Glasg.

Maryborough, Queensland, Australia.

explains many of the phenomena occurring in connexion with the circulatory system in a manner approved by modern science and contains numerous suggestions which will be of value in correlating the clinical aspect of altered blood pressure with physiological considerations.

◆

The British Medical Association: The Address in Surgery.

THE most interesting subject on which anyone can speak is that about which he knows most, and therefore Sir VICTOR HORSLEY acted wisely in choosing as the subject of his address at Toronto the recent progress of the surgery of the brain. Twenty years have elapsed since Sir VICTOR HORSLEY first brought forward at a meeting of the British Medical Association cases illustrating cerebral surgery, and very striking is the contrast between the state of our knowledge of the surgical aspect of this region of the body at that time and at present. As Sir VICTOR HORSLEY has for many years formed one of the main objects of attacks by antivivisectionists it is clearly nothing more than his due that it should be recognised that very much of the success which has attended the evolution of the surgery of the brain is due to his experiments on animals; in no other way could the progress have been so assured and so great than in that followed by him and the group of physiologists and pathologists associated with cerebral surgery. Even with regard to the anæsthesia for operations on the central nervous system the ultimate choice of one anæsthetic rather than another has been based on experiments on animals. In all cases it has been necessary by observations on human beings to confirm and extend the broad principles thus obtained, but without the laboratory work the difficulties would possibly have been insurmountable.

Too long has it been customary to look upon operative procedures on the brain or spinal cord as a last resource—this may be called the essential message of Sir VICTOR HORSLEY'S address. Months and even years are spent on medicinal treatment, and when those in charge of the case have to confess utter failure, then, and not till then, the surgeon is called in and asked, and expected, to accomplish miracles. What can be hoped from surgery in a case where optic neuritis has lasted for nine or even 13 years? And yet Sir VICTOR HORSLEY has been requested to operate in such cases and to remove tumours which have destroyed vision years before. All, or nearly all, the harmful results of cerebral growths are due to the pressure exerted on neighbouring structures. At first the only effect of this pressure is to interfere with the function of the part compressed, to delay or forbid the transmission of nerve currents, to prevent the due working of nerve centres, or by interference with the circulation of a portion of nerve tissue to put an end to its action. Soon, however, pressure on the nerve tissue leads to atrophy. Such a result will follow a constant pressure in any organ of the body, but it is especially rapid and certain when the compressed tissue is so complex and delicate a structure as that of the central nervous system. Every day that unnecessarily delays the removal of the pressure tends to diminish the possibility of the return of function or to limit the completeness of the recovery. Even when the pressure is of a nature removeable by medicinal means, as in the case of a syphilitic gumma, the medicinal means must be employed early and energetically if good is to result. An immense responsibility rests therefore on those who counsel unnecessary delay in resorting to surgical methods for the relief of cerebral pressure. The medicinal treatment may reasonably ask for a trial before any call is made for surgical aid, and, with the idea of getting some general line of procedure for cases which must offer many general similarities, it has been suggested that surgical interference may be postponed for three months. The delay in the opinion of many is sufficient. It cannot, on the one hand, be looked upon as too short a time, nor can it be urged, on the other hand, that the time has been unduly prolonged. But we think that when three months have run their course no excuse can be offered for further delay, and the assistance of the surgeon should be invited. It must not be imagined that in all cases so long a period should be allowed to elapse before the surgeon is called upon for assistance, for it may be recognised at a much earlier period that medicine can do no more, but where no indications of urgency exist the delay is reasonable. Sir VICTOR HORSLEY, however, feels that he may lay down a definite rule that in no case of optic neuritis (unless of toxic or anæmic origin) should the process be allowed to continue after it has once been diagnosed, for if it be left unrelieved, and blindness results therefrom, a heavy responsibility rests on anyone who failed to advise such a simple proceeding as opening the dura mater.

For operation on the brain there is little that is special in the preparation of the patient, though calcium chloride appears to be of use where much oozing is expected, as in the case of perforating tumours of the skull. As to the anæsthetic the use of morphine hypodermically in conjunction with chloroform has been abandoned, for it has been found that the morphine was harmful both from its effect on the alimentary canal and from its depressing influence on the respiratory centre. Ether is inadmissible, in spite of it being safer than chloroform, because it raises the blood pressure and increases the venosity of the blood, and this occurrence may cause much additional and troublesome hæmorrhage. Chloroform, on the other hand, causes a fall of blood pressure and so less hæmorrhage occurs. It is, however, distinctly more dangerous than ether, while all cases of increased intracranial tension are especially liable to sudden death from paralysis of the respiratory centre. It is therefore essential that some apparatus should be employed by which a definite percentage of chloroform may be given. Sir VICTOR HORSLEY always uses the Vernon-Harcourt apparatus, the merits of which are known to all our readers. A point of great importance in the administration of chloroform in these cases, or indeed of any anæsthetic, is that the depth of narcosis, and therefore the amount of anæsthetic administered, should vary with the sensitiveness of the structures about to be divided. 2 per cent. of chloroform vapour will induce anæsthesia and allow the division of the skin and the reflexion of the scalp flap, for this is the most painful part of the operation, but 1 per cent. will suffice for the removal of the bone, for bone is less disease to our right appreciation of the problems discussed by Sir JAMES BARR. There is a great tendency when dealing with circulatory disorders to adopt therapeutic measures which act on the heart only; drugs are given which increase the cardiac power in order to stimulate the circulation. It is too often forgotten that the heart may be relieved in two ways—either by the administration of drugs acting as a central stimulus, or by reducing the resistance in the peripheral circulation which the heart has to overcome. The latter procedure is as important in many cases as the former, but at any rate until quite modern times it has not received the same attention. Sir JAMES BARR, who may be congratulated upon being a pioneer, points out that writers hitherto on this subject have almost invariably traced the circulation from the centre to the periphery, and it is worthy of notice that although the numerous treatises on diseases of the heart and aorta have received many annual additions with regularity, until recent years a careful study of the peripheral circulation has been largely left to physiologists—the physician's need of such information being insufficiently recognised. It was a happy thought of the lecturer to reverse the usual procedure, and it has resulted in an address of distinct originality.

Sir JAMES BARR refers to many interesting points connected with the functions and structure of the smaller arteries and veins and of the capillaries, and his lecture will serve to remind many of our readers how indefinitely the scope of systemic medicine is now enlarging. In considering the capillary circulation, he duly insists on its importance as the medium through which the interchange of nutritive pabulum and gases takes place between the blood and tissues, while he points out that the exact conditions under which this circulation is carried on have not until recently been fully comprehended; yet knowing their physiological functions we can all see that a careful study of these little tubes is of as much importance as study of the heart itself. It will probably be a new fact to many to learn that, although in very plethoric individuals and in cases of polycythæmia the capillaries of the body are fairly replete, in ordinary subjects, and especially in those of neurotic temperament, perhaps *not* a third of the capillaries are full at any one moment. From the fact, then, that in normal circumstances a sufficient quantity of blood cannot pass through the arterioles to keep the enormous capillary bed full the lateral pressure and the velocity in the capillaries must be ever-varying quantities. Sir JAMES BARR'S observations on these two forces require careful attention in order to appreciate them fully, but his contentions are sound and based on accurate scientific reasoning. From a clinical point of view one fact is particularly important—namely, that the pressure stands in direct relation to the freedom of the inflow and the obstruction to the outflow. To illustrate this point a simple example was taken. In cases of local syncope the lumen of the arterioles supplying the affected district is obliterated and the capillary pressure is reduced to *nil*. If measures are taken to dilate the arterioles, the mass of blood in the capillaries is augmented, the pressure rises, and the fall in the pressure-gradient between the arteries and capillaries becomes more gradual. The velocity of the blood in the capillaries is also considered in a similarly graphic manner. Sir JAMES BARR shows that it depends chiefly on the potential in the arteries—the higher the arterial pressure the greater the velocity in the arterioles and capillaries. As a general rule it may be assumed that high arterial tension drives the blood through the arterioles and capillaries with great velocity. If, however, only the arterioles of a small area, such as the hand, be contracted the general arterial pressure is not affected; the blood travels in the direction of least resistance, the supply to the hand is diminished, and although the capillary pressure is lessened the velocity is not increased. The regulation of the velocity in the capillaries is a matter of considerable clinical importance. When the velocity is reduced to one millimetre or less per second the blood is surcharged with carbonic acid, the skin or organ supplied becoming of a dusky hue. If the capillary velocity be increased this appearance disappears. To give an example: in cases of cardiac failure with or without any obstructive lung disease, there is often cyanosis of the arms and upper parts of the body. In order to relieve this venous condition of the blood, and to assist in restoring the normal respiratory exchange, oxygen gas is frequently administered. Sir JAMES BARR rightly suggests, however, that the correct treatment would be a judicious cardiac tonic, that is to say, the essential requirement is the administration of drugs which *increase* the velocity of the capillary circulation.

Turning to another subject—the resistance offered to the arterial flow and consequently to the heart, Sir JAMES BARR discussed the views held by various investigators as to whether this resistance was due to the viscosity of the blood or whether it was situated in the arterioles or in the capillaries. We agree with him when he maintains that the barrier to the outflow from the heart exists in the small arteries and arterioles which are governed by vaso-motor action. His arguments for upholding this opinion are strong and, to our mind, convincing. The main reason he gives is that there is very little fall in the pressure-gradient from the large to the small arteries, whereas in the very small arteries and in the arterioles, where he maintains that the resistance exists, there is a very great fall in the pressure and an increased velocity. If, says Sir JAMES BARR, the capillaries formed the first line of *resistance*, the fall in the pressure-gradient in the arterioles would be much *more* gradual, and high arterial pressure would be associated with high capillary pressure. As is well known, however, the reverse is the case. We would point out that the fact of the resistance being in the arterioles must be regarded as an important clinical point. In order to relieve a dilated heart, not only must the heart itself be stimulated but drugs must be given which dilate the arterioles so as to lessen the resistance which the heart has to overcome. It is this kind of simple lesson, not dogmatic but reasoned out, for which the busy practitioner is grateful, and for many such dicta we warmly recommend Sir JAMES BARR'S address to the attention of our readers. He has added to the valuable work which has been carried out during recent years by various observers in regard to altered blood pressure, its causes and effects. Some time must elapse before the full significance of these researches can be appreciated, but this *address*

Thus the milk of the rabbit contains 10·4 per cent. of proteid and 2·4 per cent. of ash and the weight of the baby rabbit is doubled in about seven days. The human animal is at the other end of the scale, for human milk shows *only 1·0 per cent. of proteid* and 0·2 per cent. of mineral matter, and accordingly the human baby's weight takes as many as 180 days to double. The kid's weight is doubled in 19 days and goats' milk contains 4·3 per cent. of proteid and 0·8 per cent. of mineral matter. There can be no excuse for mis-stating the composition of goats' milk as appears to have been done in the case quoted by our correspondent, and it is certainly a misrepresentation of fact to state (if it was so stated) that "goats' milk was worse than skimmed milk and did not contain sufficient fat or sugar." As a matter of fact, goats' milk is richer in proteids and mineral salts than genuine cows' milk and contains usually as much sugar and rather more fat. Goats' milk therefore as a substitute for cows' milk or human milk cannot be condemned on the grounds of its chemical composition, but its adaptability for the human infant's needs is another matter.

FLY LIFE AND INFECTIVE DISEASE.

THE fly, like the worm, has its place and function in the economy of nature both for good and for evil. What the worm is to the soil the fly is to the air, exercising a depurative influence by its absorption of effluvia which, directly inhaled, would be mischievous, even fatal, to man. On the other hand, the fly may be the carrier and transmitter of pathogenic organisms which, introduced by puncture or even simple contact into the human subject, are the proximate cause of infective disease. In 1883 Professor Angelo Celli of Rome observed that flies nourished on the typhoid bacillus transmit, by the medium of their fæces, the same malady in all its virulence—an observation amply confirmed just ten years later, in 1898, in the American concentration camps in Cuba during the war. Even prior to this a similar observation, experimentally confirmed, had been made in Hamburg in the case of cholera. Flies, during the necropsy of a victim to that disease, having alighted on the intestine, were inclosed in a glass receptacle so that the air and the movement might desiccate and neutralise the particles of choleraic virus adhering to their wings and extremities, and were thereafter placed in a tube containing liquid gelatine. In 48 hours all the plaques were covered with colonies of the *bacillus virgula*. More recently, in Paris, it was shown that flies are the principal agents in diffusing cholera at short distances, thus explaining the fact that cholera epidemics diminish in intensity during winter when fly life is arrested by the cold. A still more recent study in this field is that of Professor Saverio Santori of the bacteriological laboratory of the Roman commune, by which he demonstrates the fly as causing the dissemination of "infective intestinal maladies," *particularly* the summer gastro-enteritis of children in its acute form. Examining the statistics of the Italian death-rate, he found that while in the last 20 years well-*nigh all infective* diseases are on the wane some, and these the intestinal, show little or no tendency to decrease. Inferring that these ailments must be propagated by other than the usual agents, against which we neglect to guard ourselves, Professor Santori bethought him of the flies. He thereupon made a study of the "flora bacterica" contained in their digestive tube, on the tracks they left on the places over which they crawled, and on all their corporeal superficies, taking special care that the said flies came from the most frequented localities, especially from the neighbourhood of market places and hospitals. The results were surprising even to himself. He found that on the walking apparatus, the wings, the proboscides, and, in general, all over the bodies of the flies there were pathogen bacilli not only in vast quantities but of the most var forms, the latter observation seeming natural enoug when we think of the infinity of soiled substances up which the fly alights. At the same time, this variety o form in the bacilli was much less in the digestive tube one form so preponderating as to make all the othe practically non-existent. Professor Santori, in fact, fr cultures derived from flies frequenting a Roman mark place succeeded in isolating a bacillus which under th microscope appeared mobile, short and stunted, its characteristics, morphological, cultural, and biological, and pathological features corresponding exactly to that "speci micro-organismo" which Dr. G. Volpino described so months ago in the "Archivio per le Scienze Mediche" as "pathogenic agent" of the "infezioni viscerali" affect infants in summer. The importance of this identification manifest. It may explain the enormous diffusion of th gastro-intestinal malady, particularly in the summer, and also throws light on the fact that in these later years malady, unlike other infective diseases, shows little or signs of decrease. The practical, hygienic, corollary arising is, according to Professor Santori, to take measures for lessening in our habitations the number of flies and for the prompt and thorough removal the soiled or putrescent substances from which these fl transport and diffuse, in myriads, the pathogenic germs.

ŒSOPHAGEAL SYMPTOMS IN AORTIC ANEURYSM.

AT a meeting of the Société Médicale des Hôpitaux Paris held on May 4th M. Edgard Hirtz and M. H Lemaire reported an important case of aortic an with œsophageal symptoms. Rupture of an aortic aneury into the digestive tract is rare. In a period of 72 142 cases of ruptured aneurysm were reported to th Société Anatomique of Paris. In 79 of these ru occurred into the air passages and in only six into digestive tract, once into the duodenum, once into stomach, and four times into the œsophagus. A man, 55 years, was admitted into hospital on March 3rd, 1905. could not be ascertained whether he had had syphilis or no For six months he had suffered from digestive trouble At the beginning there was a little diarrhœa, but the last few weeks this had given place to tion. For two months vomiting had followed nearly meal. At first the vomiting occurred about an hour a meals, then it occurred earlier, and finally it took the f of regurgitation. After taking a few mouthfuls of food patient had to get up in order to eject what he h swallowed. This always occurred in the case of liquids b solids were often retained. Deglutition was not painful did not appear to be difficult. For four months the patie had been losing flesh and strength. On admission he l cachectic and the conjunctivæ and face had a sub-icter tinge. There was myosis without inequality of pupils. the upper part of the epigastrium some deep and lumps were felt. On taking a glass of milk the patie vomited it after some seconds and in the meantime abunda salivation occurred. The urine was increased in q and contained a trace of albumin. The area of car dulness was increased, especially to the left. The a beat was in the fifth space outside the nipple Auscultation showed a "*bruit de galop*" on the left and a resounding second sound at the base. The arteri were atheromatous; the radial and femoral pulses were equal. Abundant salivation always followed the taking of food but occurred at no other time. The patient complained of great thirst which he could not quench. The existence of painl œsophageal vomiting with abundant salivation led to th sensitive. The dura mater has a fair nerve-supply from the trigeminal, and when the dura mater is divided a slightly deeper anæsthesia is needed. That accomplished however, less than 0·5 per cent. will be amply sufficient for most operations on the brain substance, for the encephalon is for the most part little sensitive. Sometimes, indeed, the chloroform may be entirely cut off for 10 or 15 minutes, and in one case Sir VICTOR HORSLEY was able to operate for 20 minutes without chloroform on a child with a cerebellar tumour.

In all intracranial operations it is of the first importance to arrest hæmorrhage, but the oft-tried expedient of tying a main artery such as a carotid does not meet with Sir VICTOR HORSLEY'S approval. For the capillary and arteriole oozing he finds nothing better than hot irrigation, and for this purpose the temperature of the lotion should not be allowed to fall below 110° F., while it should not exceed 115°. Another expedient of value in the arrest of venous and capillary oozing is the inhalation of oxygen, for this lowers immediately the pressure in the veins, the bleeding ceasing rapidly as the dark purple of the oozing blood changes to bright scarlet. Much of the danger from shock in these operations can be avoided by dividing the operation into two stages with an interval of some five days; for it is certain that it is the opening of the skull which causes most shock by producing general depression of nerve energy and alteration in the circulation. If we may judge by statistics, the danger in these operations varies greatly with the region involved, most deaths occurring when the cerebellar region is dealt with and least when the motor area is affected. It is, moreover, clear that in operations designed to remove an excess of intracranial tension shock is least fatal when, a correct diagnosis having been made, the skull has been opened immediately over the affected part, and the tumour has been easily removed. Conversely when an incorrect diagnosis has been made and the skull has been opened at a distance from the tumour, which was therefore not removed, a much higher rate of mortality has occurred.

Of the danger of sepsis in operations on the contents of the skull no difference of opinion can exist, but especial precautions should be taken in these cases, and Sir VICTOR HORSLEY points out that a weak antiseptic lotion is desirable for the irrigation fluid; that the subsequent dressing should be antiseptic (some mercurial salt being employed) and not merely aseptic; and lastly, that drainage should be employed as little as possible, for every drain forms a probable channel for the admission of germs. It is important to displace as slightly as possible the cerebral tissues, for even if they have not been visibly damaged permanent harm appears to result from displacing portions of the brain; and all pressure exerted on brain substance, as in raising the frontal lobe, must be of the utmost gentleness and applied slowly. It has been suggested that a lateral lobe of the cerebellum may be removed without danger for the purpose of reaching deeply seated tumours, and so far as experience goes very little harm seems to result, but it is an unnecessary mutilation and should therefore be avoided, even though we are unable to trace to it any harmful results. Finally, in many cases it appears to be sufficient for removing the effects of pressure to open the skull, though it is generally necessary to divide the dura mater also, and this may be effective in relieving symptoms even though it may not be possible to remove the tumour causing the increased pressure. In several cases Sir VICTOR HORSLEY has laid bare gliomata and having found them inoperable he has closed the wound. From the date of the operation the symptoms have steadily diminished and ultimately disappeared. Without venturing to suggest any adequate explanation of the facts, it cannot be doubted that complete or almost complete recovery does follow in many of these cases.

The conclusions to be drawn are that in the last 20 years great progress has been made in this the youngest, or almost the youngest, branch of surgery; we have learned to avoid or to counteract many of the dangers which beset the path of the operator on the brain and the field of utility has been widely extended. Much has, indeed, been done, much still remains to do, and as in the past no small share of the achievements already gained are due to Sir VICTOR HORSLEY, so in the future we may with confidence expect that he will be one of our forerunners along this most difficult yet most encouraging branch of surgery.

Annotations.

"Ne quid nimis."

GOATS' MILK FOR INFANTS.

IN a letter which appears in our correspondence columns this week an interesting point is raised by the writer in regard to the suitability of goats' milk for infant feeding. There is evidently a wide diversity of opinion on this question judging from the totally opposite views taken by different authorities on dietetics in general. One writer, indeed, on one page of his book regards goats' milk with favour in infant feeding, while on another page he refers to its indigestibility. Thus, he says, "it [i.e., goats' milk] is the most highly nutritious of these milks but it is the least digestible." In the same book it is written in another place: "The reason why the milk of the ass and even that of the goat will agree with the human infant when cow's milk disagrees would appear to be owing to their different manner of clotting when they come into contact with the gastric juice. Cow's milk has a tendency to coagulate in the infant's stomach into large, firm, cheese-like masses which are apt to cause much gastro intestinal irritation, whereas ass's and goat's milk form a loose flocculent curd like human milk." Another authority writes: "Goats' milk is a strong milk, stronger even than cows', and in no way suited for use in infancy," and another that "the coagulation [of goats' milk] obtained by acid or rennet is more solid and is harder than that from cow's milk." As to the chemical composition of goats' milk in its relation to human or cows' milk there ought not to be, of course, two opinions and yet one authority writes, "The milk of the goat, as a rule, contains more cream than that of the cow and rather less albuminous matter," while another says, "goats' milk is richer in albuminates and fats than human milk and even than cows' milk." The latter writer is correct judging from the average figures given in a number of analyses by various authoritative observers. The composition of a milk would appear to depend upon the rate of growth of the animal for which it is intended, and the variations occur chiefly in regard to the proteids and mineral constituents. Heubner, for instance, showed that as the proportion together of proteid and mineral matter increased in milk, so the time taken to double the weight of the animal was diminished.

physician who has to forecast chances of life, and so on. The question of ultimate prognosis is a difficult one, and as Dr. Fox remarks, many years' experience will be needful in order to decide with certainty whether these cases eventually become the subject of progressive disease. The responsibilities of examiners for life insurance in this matter are considerable.

KING EDWARD VII. SANATORIUM.

THE King Edward VII. Sanatorium, which has now been open some two months, is, we are glad to know, in satisfactory working order, as many suitable cases being under charge as has been thought prudent to commence with. But there appears to be some doubt both among the members of the medical profession and of the general public as to the class of cases eligible for admission to this institution. We are requested to state that by the wish of His Majesty the King the sanatorium is primarily intended for the accommodation of those persons of slender means among the educated classes who are suffering from early pulmonary tuberculosis, and who are unable to pay the charges of private sanatoriums. For such patients 86 beds are reserved at a charge of two guineas per week, both sexes being admitted in equal numbers. It is also the King's wish that those persons of larger means who can afford to pay for treatment should not be entirely excluded from the advantages to be derived from the institution, and 14 beds have accordingly been reserved for them, for which a charge of eight guineas a week is made.

COEXISTENCE OF DISEASES.

WE have been asked by an Australian correspondent whether any especial effect is produced on patients suffering from malignant disease or tuberculosis by the specific infectious diseases, such as typhoid fever, measles, and small-pox. Patients the subject of malignant disease are usually at an age when acute specific fevers are uncommon and we are not aware that any statistics on the subject exist. As a matter of interest, however, we may refer to the supposed effect of erysipelas on sarcoma. Cases have been recorded in which a patient suffering from sarcoma has been attacked with erysipelas, with the result that the tumour disappeared. Such instances are extremely rare and may perhaps be attributed to mere coincidence. Nevertheless, observers were led to attempt to treat sarcoma by injections of the products of the pathogenic organism of erysipelas. Coley used a fluid containing the combined toxins of the streptococcus, of the bacillus erysipelatis, and of the micrococcus prodigiosus. Fehleisen also tried the inoculation of erysipelas. The effect of both these forms of treatment seemed to produce a local and not a general modification. The result of an infectious disease occurring in a tuberculous subject does not essentially differ from that found when a healthy subject is attacked, except that in the *former* the powers of resistance are less and not infrequently an intercurrent affection is so badly borne as to threaten seriously the patient's life. Particularly is this the case when a patient suffering from pulmonary tuberculosis becomes infected with influenza or pneumonia. That two or more infectious diseases may coexist in the same individual is generally recognised, and clinical experience would tend to show that the presence of one disease in the body increases the liability to the infection of another. We are not aware, however, that tuberculous subjects are more susceptible to infectious diseases than are healthy people. In this connexion Dr. F. F. Caiger's statistics[1] in regard to various infectious fevers attacking patients already suffering from scarlet fever are interesting, but, as he himself states, cannot be taken as an accurate expression of the proportionate liability to coexistence. The diseases most frequently complicating scarlet fever are diphtheria, chicken-pox, and measles, but care must be taken not to confuse the exudation frequently seen in the throat in scarlet fever with diphtheritic membrane. The subject of mixed infections is an interesting one and merits more attention than has hitherto been accorded to it.

A BAD CASE OF OVERLYING.

AT a recent inquest at Bermondsey on the body of a child 12 days old the following story was told. Ten days after the child's birth the parents celebrated the event by holding a "sing-song," at which they both got drunk. On the following morning, or on the morning after that, a neighbour heard children crying and going into the room found the parents in a drunken sleep with the infant and three other children in the bed with them. The neighbour released one of the children upon whom the mother was lying and left. Later she heard that when the parents had roused themselves from their drunken sleep they had found the infant dead. The jury in this case returned a verdict of accidental death and requested the coroner to censure the parents. That they were greatly impressed by the coroner's censure or deeply grieved by the loss of their child seems improbable. They are rid of the responsibility and expense of bringing up their offspring, and in the course of the year other fathers and mothers will act as they did—get drunk and smother a baby—with no further result than having to attend an inquest and listen to a reproof administered by the coroner. With all respect for what may be done by instruction and admonition it will occur to many that the indictment of a few such parents for manslaughter, with a stiff sentence of imprisonment upon conviction, might bring about the saving of lives. It is difficult to believe that facts such as those mentioned above do not constitute the crime of manslaughter or that a jury before whom they were proved would refuse to find a verdict of guilty from any sympathy with the accused.

RUPTURE OF THE SPLEEN IN A CASE OF STRYCHNINE POISONING IN A MALARIAL SUBJECT.

IN the *Archives Générales de Médecine* of August 7th Dr. Poirson has reported the case of a woman who was given during an attack of malarial fever about half a gramme of a powder supposed to be quinine. About three-quarters of an hour later she called for help and was found in a state of convulsions with opisthotonos. About one and a quarter hours after taking the powder she died in a state of syncope. She was not under medical observation at any period of the attack. The necropsy showed an enlarged liver which extended four fingers' breadth below the ribs. The peritoneal cavity contained two litres of dark blood. The spleen was about thrice its normal size, very soft, and engorged with blood. There was no perisplenitis or adhesions. At the lower end of the internal border of the spleen was a rupture six centimetres long, of cuneiform shape, and covered with adherent clot. Seven centigrammes of sulphate of strychnine were extracted from the viscera. Death was evidently due to syncope, the result of hæmorrhage from the ruptured spleen and occurred before the poison had time to prove fatal. Spontaneous rupture of the spleen is a well-recognised, though rare, occurrence in malarial fever. In all the cases, as in the present instance, the spleen presented pathological changes, such as hypertrophy, softening, congestion, and friability. With the spleen in such condition an diagnosis of stricture of the œsophagus. The lumps felt in the epigastrium seemed to point to malignant disease of the cardia. But the regurgitation followed closer and closer upon deglutition and the patient was not compelled to diminish more and more the size of the bolus; moreover, the regurgitation was almost selective for liquids. These facts were not in accord with the existence of a progressive malignant stricture of the lower end of the œsophagus. The hypothesis of pressure on the œsophagus by a mediastinal tumour was also entertained. On March 8th there was a severe attack of hæmatemesis; bright red blood was ejected without any effort of vomiting. Syncope followed and about an hour later a stool consisting of black clot was passed. On the following day a similar attack of hæmatemesis occurred and proved fatal. The necropsy showed a greatly enlarged heart and induration and insufficiency of the aortic valves. The aorta was uniformly dilated from the arch to just above the diaphragm, its diameter being more than five centimetres. At the diaphragm was a spherical aneurysm of the size of the fist. It was intimately adherent to the œsophagus, into which it had perforated. The lumen of the œsophagus was but little contracted by the aneurysm. The left pneumogastric nerve was involved in the adhesions between the œsophagus and the aneurysm and was exposed in the communication between them. It is noteworthy that the only symptoms of the aneurysm before rupture were the "œsophageal vomiting" (regurgitation) and the salivation after taking food. M. Hirtz and M. Lemaire thought that the latter was an œsophago-salivary reflex. M. Antony has pointed out the existence of this reflex in cancer of the œsophagus. The survival of the patient after the rupture of the aneurysm (indicated by the first attack of hæmatemesis) is also noteworthy. So, too, are the facts that there was no mechanical obstacle to deglutition and that liquids were not so well swallowed as solids. Dysphagia is rare in aortic aneurysm. In this case both the salivation and the vomiting appeared to be reflex effects of irritation of the exposed pneumogastric nerve during deglutition. Spasm of the œsophagus was excited and was the obstacle to deglutition. This explains the selective character of the vomiting.

KISSING THE BOOK.

THE question of the possibility of infection by the kissing of the dirty copy of the Gospels in the English form of taking the oath in court or elsewhere has again been the subject of much correspondence in the daily press. Our own columns have for years borne witness to the unpleasantness and to the risk of infection which the kissing of a book which has been kissed by several hundreds of other people entails, and we have again and again drawn attention to the provision of the Oaths Act of 1888, of which Section 5 runs as follows:—

> If any person to whom an oath is administered desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland he shall be permitted to do so and the oath shall be administered to him in such a form and manner without further question.

Apparently, however, certain officials are still ignorant of, or desire to ignore, the provisions of this Act. Thus a correspondent, writing in the *Times* of August 17th, says that he recently attempted to be sworn in the Scottish fashion before a London county court judge, but that the judge showed much reluctance to accept the oath and he, the correspondent, therefore did not press the point. About 11 years ago his honour Judge Emden placed notices in his court drawing attention to the fact that any person who had to be sworn might be so sworn in the Scottish fashion, and it was recently announced that the chief clerk of the Lambeth police court had given instructions that all witnesses are for the future to be given the option of being sworn in the Scottish fashion. Every British subject is supposed to be acquainted with the laws of his country, so, legally speaking, a person has only himself to blame who does not avail himself of the provisions of the Act of 1888; but it is difficult for the ordinary person to go against the apparent wish of a judge or of a magistrate that the Scottish form should not be employed. We think it would be well that all persons exercising judicial functions, if they do not feel themselves bound to go so far as to give witnesses, without their demanding it, the option of being sworn in the Scottish fashion, should at least exhibit a notice in their courts on the model of that adopted by Judge Emden.

A QUACK SENT TO PRISON.

Abraham Levine, described as a tailor, was sentenced at the recent County of London Sessions to 15 months' hard labour for an assault upon an epileptic girl whom he had undertaken to cure. Evidence was given that he had for some time made money by pretending to treat disease, particularly epilepsy, and also that he had obtained £2 from a woman by promising to bring back her husband who had deserted her. He was certified for deportation at the expiration of his sentence. Apparently if Levine had not taken advantage of the opportunity afforded to him by a helpless girl being placed in his power by her mother in order to assault her he would have continued to make a wholly dishonest livelihood undisturbed. He possessed no medical qualifications, but so long as he made no pretence of being a registered medical practitioner he might claim to be able to cure any disease, might extract money, and might endanger the lives of his dupes to an extent upon which the law imposed no limits.

HÆMATOGENOUS ALBUMINURIA.

MANY observers have recorded the fact observed in soldiers, cadets, children, and others, who were apparently healthy, that albumin is occasionally found in the urine. The same difficulty is sometimes experienced in examinations for life insurance. A young man applies for insurance. On examination everything is found to be satisfactory except that a trace of albumin is discovered in the urine. The urine is not continuously of low specific gravity and the albumin (serum albumin) is often present only at intervals following the rise from bed or succeeding a meal. Or it comes on after muscular exertion, cold bathing, or emotional strain. The late Sir Andrew Clark stated that he frequently found albuminuria in young men who had been working hard for their examinations. This condition is the subject of a paper in this issue of THE LANCET, by Dr. R. Hingston Fox, under the title of "Hæmatogenous Albuminuria." He refers to the researches of Sir A. E. Wright, who has produced strong grounds for the belief that this form of albuminuria is due to a disorder of the blood, the outstanding feature of which is lessened coagulability. Dr. Fox makes some interesting observations on the control of the albumin by the use of calcium lactate. This is an important point which is not generally recognised. Dr. Fox used the test in 16 cases of albuminuria indiscriminately. In seven the albumin disappeared or was reduced to a small trace after the taking of the lactate. Dr. Fox believes that these were all instances of hæmatogenous albuminuria. In the remaining nine the albumin persisted; in most of these cases signs of kidney disease were present. Notes of the cases are given by Dr. Fox and for details we refer our readers to the original paper. This clinical test is of considerable importance, and if the observations can be further corroborated a valuable aid will be offered to diagnosis. This form of transient albuminuria is not immediately of serious import, but its presence is always embarrassing to the physician who has to forecast chances of life, and so on. The question of ultimate prognosis is a difficult one, and as Dr. Fox remarks, many years' experience will be needful in order to decide with certainty whether these cases eventually become the subject of progressive disease. The responsibilities of examiners for life insurance in this matter are considerable.

KING EDWARD VII. SANATORIUM.

THE King Edward VII. Sanatorium, which has now been open some two months, is, we are glad to know, in satisfactory working order, as many suitable cases being under charge as has been thought prudent to commence with. But there appears to be some doubt both among the members of the medical profession and of the general public as to the class of cases eligible for admission to this institution. We are requested to state that by the wish of His Majesty the King the sanatorium is primarily intended for the accommodation of those persons of slender means among the educated classes who are suffering from early pulmonary tuberculosis, and who are unable to pay the charges of private sanatoriums. For such patients 86 beds are reserved at a charge of two guineas per week, both sexes being admitted in equal numbers. It is also the King's wish that those persons of larger means who can afford to pay for treatment should not be entirely excluded from the advantages to be derived from the institution, and 14 beds have accordingly been reserved for them, for which a charge of eight guineas a week is made.

COEXISTENCE OF DISEASES.

WE have been asked by an Australian correspondent whether any especial effect is produced on patients suffering from malignant disease or tuberculosis by the specific infectious diseases, such as typhoid fever, measles, and small-pox. Patients the subject of malignant disease are usually at an age when acute specific fevers are uncommon and we are not aware that any statistics on the subject exist. As a matter of interest, however, we may refer to the supposed effect of erysipelas on sarcoma. Cases have been recorded in which a patient suffering from sarcoma has been attacked with erysipelas, with the result that the tumour disappeared. Such instances are extremely rare and may perhaps be attributed to mere coincidence. Nevertheless, observers were led to attempt to treat sarcoma by injections of the products of the pathogenic organism of erysipelas. Coley used a fluid containing the combined toxins of the streptococcus, of the bacillus erysipelatis, and of the micrococcus prodigiosus. Fehleisen also tried the inoculation of erysipelas. The effect of both these forms of treatment seemed to produce a local and not a general modification. The result of an infectious disease occurring in a tuberculous subject does not essentially differ from that found when a healthy subject is attacked, except that in the former the powers of resistance are less and not infrequently an intercurrent affection is so badly borne as to threaten seriously the patient's life. Particularly is this the case when a patient suffering from pulmonary tuberculosis becomes infected with influenza or pneumonia. That two or more infectious diseases may coexist in the same individual is generally recognised, and clinical experience would tend to show that the presence of one disease in the body increases the liability to the infection of another. We are not aware, however, that tuberculous subjects are more susceptible to infectious diseases than are healthy people. In this connexion Dr. F. F. Caiger's statistics[1] in regard to various infectious fevers attacking patients already suffering from scarlet fever are interesting, but, as he himself states, cannot be taken as an accurate expression of the proportionate liability to coexistence. The diseases most frequently complicating scarlet fever are diphtheria, chicken-pox, and measles, but care must be taken not to confuse the exudation frequently seen in the throat in scarlet fever with diphtheritic membrane. The subject of mixed infections is an interesting one and merits more attention than has hitherto been accorded to it.

A BAD CASE OF OVERLYING.

KISSING THE BOOK.

THE question of the possibility of infection by the kissing of the dirty copy of the Gospels in the English form of taking the oath in court or elsewhere has again been the subject of much correspondence in the daily press. Our own columns have for years borne witness to the unpleasantness and to the risk of infection which the kissing of a book which has been kissed by several hundreds of other people entails, and we have again and again drawn attention to the provision of the Oaths Act of 1888, of which Section 5 runs as follows:—

> If any person to whom an oath is administered desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland he shall be permitted to do so and the oath shall be administered to him in such a form and manner without further question.

Apparently, however, certain officials are still ignorant of, or desire to ignore, the provisions of this Act. Thus a correspondent, writing in the *Times* of August 17th, says that he recently attempted to be sworn in the Scottish fashion before a London county court judge, but that the judge showed much reluctance to accept the oath and he, the correspondent, therefore did not press the point. About 11 years ago his honour Judge Emden placed notices in his court drawing attention to the fact that any person who had to be sworn might be so sworn in the Scottish fashion, and it was recently announced that the chief clerk of the Lambeth police court had given instructions that all witnesses are for the future to be given the option of being sworn in the Scottish fashion. Every British subject is supposed to be acquainted with the laws of his country, so, legally speaking, a person has only himself to blame who does not avail himself of the provisions of the Act of 1888; but it is difficult for the ordinary person to go against the apparent wish of a judge or of a magistrate that the Scottish form should not be employed. We think it would be well that all persons exercising judicial functions, if they do not feel themselves bound to go so far as to give witnesses, without their demanding it, the option of being sworn in the Scottish fashion, should at least exhibit a notice in their courts on the model of that adopted by Judge Emden.

A QUACK SENT TO PRISON.

Abraham Levine, described as a tailor, was sentenced at the recent County of London Sessions to 15 months' hard labour for an assault upon an epileptic girl whom he had undertaken to cure. Evidence was given that he had for some time made money by pretending to treat disease, particularly epilepsy, and also that he had obtained £2 from a woman by promising to bring back her husband who had deserted her. He was certified for deportation at the expiration of his sentence. Apparently if Levine had not taken advantage of the opportunity afforded to him by a helpless girl being placed in his power by her mother in order to assault her he would have continued to make a wholly dishonest livelihood undisturbed. He possessed no medical qualifications, but so long as he made no pretence of being a registered medical practitioner he might claim to be able to cure any disease, might extract money, and might endanger the lives of his dupes to an extent upon which the law imposed no limits.

HÆMATOGENOUS ALBUMINURIA.

MANY observers have recorded the fact observed in soldiers, cadets, children, and others, who were apparently healthy, that albumin is occasionally found in the urine. The same difficulty is sometimes experienced in examinations for life insurance. A young man applies for insurance. On examination everything is found to be satisfactory except that a trace of albumin is discovered in the urine. The urine is not continuously of low specific gravity and the albumin (serum albumin) is often present only at intervals following the rise from bed or succeeding a meal. Or it comes on after muscular exertion, cold bathing, or emotional strain. The late Sir Andrew Clark stated that he frequently found albuminuria in young men who had been working hard for their examinations. This condition is the subject of a paper in this issue of THE LANCET, by Dr. R. Hingston Fox, under the title of "Hæmatogenous Albuminuria." He refers to the researches of Sir A. E. Wright, who has produced strong grounds for the belief that this form of albuminuria is due to a disorder of the blood, the outstanding feature of which is lessened coagulability. Dr. Fox makes some interesting observations on the control of the albumin by the use of calcium lactate. This is an important point which is not generally recognised. Dr. Fox used the test in 16 cases of albuminuria indiscriminately. In seven the albumin disappeared or was reduced to a small trace after the taking of the lactate. Dr. Fox believes that these were all instances of hæmatogenous albuminuria. In the remaining nine the albumin persisted; in most of these cases signs of kidney disease were present. Notes of the cases are given by Dr. Fox and for details we refer our readers to the original paper. This clinical test is of considerable importance, and if the observations can be further corroborated a valuable aid will be offered to diagnosis. This form of transient albuminuria is not immediately of serious import, but its presence is always embarrassing to the all soluble toxins. Sterile normal salt solution was added to the sediment in certain proportions. It was this "suspension" that Dr. Paterson employed first in animals and then in patients, in order to test its therapeutic effects. He gives a short account of five cases in which he tried it, and the results are encouraging. He wisely does not claim more than this. The number of cases is far too small to justify any positive conclusion, and sufficient time must elapse to afford opportunities of observing the subsequent progress of the patients. It may be noted that the majority of Dr. Paterson's cases consisted of those forms of tuberculosis which usually come under the notice of the surgeon. We agree with him that his results fully justify further investigation.

HOSPITAL ABUSE AND SUBSCRIBERS' LETTERS.

THE system of issuing letters of recommendation to the subscribers to a hospital and admitting for treatment only patients whom they recommend has been weighed in the balance and pretty generally found wanting. Few, if any, of our London general hospitals carry out the method with any approach to strictness, and even at the special institutions there are signs that the day of such letters is passing. In truth, as generally worked the system is indefensible. Yet if it were carried out ideally it would possess at least one merit as a check on abuse of the charities concerned by those able to pay for medical attendance. In a letter to the *Daily Mail* the Rev. Richard Free, vicar of St. Clement's, Fulham, suggests that no applicant ought to receive a hospital letter unless he bring a recommendation from the medical man who has been attending him, or has at least given notice to his medical man that he intends applying for hospital treatment. The suggestion is certainly reasonable, though it does not apply to any applicant who has not already received medical attendance. Especially desirable is it that those who have letters to distribute should make inquiries as to the circumstances of applicants and their ability to pay for treatment at home. But we fear that there is little hope of any radical alteration in the habits of subscribers to hospitals, the vast majority of whom clearly think that when they have paid their subscription and received their letters they are called upon to take no further trouble as almoners of their own charity. Consequently, as there is little chance of the letter system being mended, we can only hope that it may be ended soon at all hospitals and replaced by some other arrangement which will supply the safeguards against abuse which are so clearly necessary.

NEOFORMANS VACCINE FOR MALIGNANT GROWTHS.

THE latest phase in the treatment of malignant growths is the employment of neoformans vaccine. Doyen of Paris some time ago described a micrococcus neoformans in new growths, especially in malignant new growths. He also employed a serum prepared from this micrococcus for the treatment of carcinomata, but although he himself claimed to have obtained some improvement from its use in certain cases others who followed his method of using the serum were unable to endorse his claims. A few months ago we published in THE LANCET[1] an account, by Dr. C. Jacobs and Dr. Victor Geets of Brussels, of the employment of a vaccine prepared also from the micrococcus neoformans, and cases were detailed in some of which marked improvement had occurred. In the June number of the *Journal of Laryngology, Rhinology, and Otology* appeared an account of a very interesting case under the care of Dr. R. H. Scanes Spicer at St. Mary's Hospital, in which a vaccine of the micrococcus neoformans was employed in the treatment of an inoperable carcinoma of the tongue and pharynx. Sir A. E. Wright directed the use of the vaccine and contributed a note on the method of treatment. The patient was a man, aged 75 years, and he was affected with a tumour of the left tonsil, the pillars of the fauces, the side of the tongue, and part of the pharynx. Large doses of potassium iodide had no effect and it was agreed by all who saw the case that it was malignant, and this diagnosis was confirmed by the microscope, for histologically the growth was found to be a spheroidal-celled carcinoma. A vaccine prepared from the micrococcus neoformans was then employed. The injections were controlled by estimations of the opsonic reaction of the blood. Improvement commenced at once, the mass visible in the fauces greatly diminished, the ulcerated surface lessened in extent, fœtor ceased, and pain and dysphagia disappeared. Most of the enlarged cervical glands subsided but one small hard gland remained. The total improvement was marvellous, not only in the local condition but also in the patient's general health. No other treatment was employed. The result was in no way claimed as a cure, but as very definite improvement followed the treatment it is at least worthy of an extended trial. The treatment has been employed by Sir A. E. Wright in four other cases; of these two have died, one is quite stationary, and the other shows marked signs of improvement. The micrococcus neoformans can certainly be obtained from a large number of tumours, and as a vaccine prepared from it appears to have a definite action on malignant growths we are justified in thinking that the micrococcus neoformans is at least one factor in the production of tumours. The micrococcus neoformans resembles closely a staphylococcus, but it differs from the latter in several respects. It gives at first very sparing cultures on agar, it grows in short bifurcating chains, it is agglutinated by normal human serum, even when this has been diluted 200 times, and lastly, a blood possessing a high opsonic power with respect to the micrococcus neoformans may possess a low opsonic index with respect to the staphylococcus.

THE TRANSMISSIBILITY OF TUBERCULOSIS BY CASEIN IN PREPARED MILK FOODS.

THE researches of Dr. Calmette, demonstrating the virulence of milk of tuberculous origin even after boiling or sterilisation, have led M. Marcel Guédras to investigate the dried milk foods of commerce in order to ascertain whether they also are capable of transmitting tuberculosis, and his results are recorded in the *Comptes Rendus* of June 25th. M. Guédras took a quantity of milk from an infected source and subjected it to the ordinary industrial method of treatment for the production of casein. The milk was first passed through a centrifugal separator, the casein was precipitated by an acid, redissolved in alkali, again precipitated, and lastly desiccated at a low temperature. Guinea-pigs fed with a solution of casein prepared in this way succumbed in 37 or 39 days, a similar result to that obtained by Dr. Calmette with sterilised tuberculous milk. It is clear therefore that the tubercle bacilli survive the various manipulations which the milk and casein undergo. It is well that the attention of hygienists should be called to the danger that may lurk in the ordinary dried milk foods of commerce. They are largely used by invalids and children on account of their high nutritive value, due chiefly to casein, but the fact that the processes through which they have passed do not destroy any tubercle bacilli that may be present renders it desirable that special care should be taken in employing only the milk of healthy cows. As regards the method of preparation, it is generally considered that the low temperature method of desiccation yields a product more nearly resembling the effort or an attack of coughing would produce contraction of the abdominal muscles and pressure on the organ sufficient to cause rupture. Rupture of an apparently normal spleen as a result of muscular contraction has been recorded. Plainchant has reported the case of a woman, not suffering from malarial fever, who died during an attack of epilepsy.[1] At the necropsy a rent was found in the fissure of the spleen and there were 250 grammes of blood in the cavity of the pelvis. If convulsions can cause rupture of an apparently normal spleen they could much more easily produce rupture of the malarial spleen. When the violent character of the convulsions produced by strychnine is considered the possibility of their causing rupture of the spleen is evident. In the present case there seems to be no doubt that they were the cause of the rupture.

A PUBLIC SLAUGHTER-HOUSE FOR THE CITY OF LONDON.

WE congratulate the Cattle Markets Committee of the Court of Common Council upon its report recommending the abolition of the private slaughter-houses attached to the Metropolitan Cattle Market and the construction in their stead of a public slaughter-house. In view of the present agitation on this subject we are not surprised at the favourable reception given to this report, and there is every reason to anticipate that the City will endeavour to be the first among the many metropolitan governing bodies to create a public abattoir. So far so good. Unfortunately the report printed, and the plan of the proposed slaughter-house which accompanies this document, give so few details that it is impossible to form an opinion as to the plan of construction recommended. It is briefly stated that the public slaughter-house for cattle and sheep will be divided into ten chambers, measuring 25 feet by 26 feet, and it is stated that "this system will enable a separate chamber to be allocated to existing tenants whose trade would appear to justify exclusive accommodation and who would be prepared to pay a 'head charge' on the animals slaughtered, with a guarantee of a minimum number per annum to be paid for. One or more chambers would be reserved for public slaughtering, the whole building being under the control of the official staff." The above proposal still bears the stamp of old errors and conceptions which we must endeavour to obliterate. It would be better to make one large hall instead of ten chambers. There is no need of exclusive accommodation unless it be to practise those tricks of trade which it is so necessary to prevent. It is all very well to say that the official staff will be in control, but how can the members of the staff see through the ten partition walls of the ten chambers? We are pleased to notice on the plan that there is a separate building with a destructor for diseased meat, but no mention is made of a separate building for the preparing of tripe and the cleaning out of intestines, yet these things represent one of the most difficult parts of the problem. But we welcome with pleasure the broad fact that the principle of a municipal slaughter-house is accepted, and that the necessity of abolishing private slaughter-houses is recognised.

MALARIA IN THE FEDERATED MALAY STATES.

IN various districts where malarial fever has caused much loss of life successful results have been obtained by the adoption of modern sanitary measures based on Major R Ross's plan for the destruction of mosquitoes. In THE LANCET of May 14th, 1904, p. 1372, we drew attention to the vast improvement that had been brought about in Ismailia, Egypt. Writing in the *Times* of August 7th of this year, Dr. Hamilton Wright gives a brief account of the measures adopted at Port Swettenham in the Federated Malay States. This port was designed by the Government of these States to replace that of Klang on the upper tidal reach of the river of the same name. Port Swettenham was jungle-covered, flooded daily by tides, and incident to an average of about 100 inches of rainfall a year. Dr. Wright had shown that the district was a pest-centre of the worst forms of malaria. On the formal opening of the port Klang was abandoned and the river closed to sea-going vessels. Severe malaria immediately broke out amongst the officials and coolies employed on the railway and shipping. A commission was at once appointed, composed of medical men and railway and works officials, and was instructed to devise measures for the suppression of malaria and for the general sanitary improvement of the port. The recommendations of the commission involved an outlay of from £10,000 to £12,000. It is to the great credit of the Government that without any hesitation it accepted these recommendations. The new port was dyked, drained, levelled, and cleared. Since these sanitary measures were initiated there has been scarcely a case of malaria at the port, and from being an unhealthy, shunned swamp the port is now sought by officials as a desirable billet. We cordially support Dr. Wright when he says that such results as this, and as those achieved at Ismailia, ought to be compelling examples to those who still doubt the findings of science in regard to malaria and other tropical diseases. Major Ross, Sir Patrick Manson, and others have been pioneers in the "antimalarial campaign," and if their efforts are supported by the Governments and local authorities in those districts in which malaria is prevalent the saving of human life and the advancement of commerce will follow.

STERILE CASEOUS MATTER IN THE TREATMENT OF TUBERCULOUS DISEASE.

IN this issue we publish a "preliminary paper" by Dr. P. Paterson on the effect produced on tuberculous lesions by the injection of some of the products of the tubercle bacillus as elaborated in the body. Numerous attempts have been made by competent investigators to separate the antitoxin of tuberculosis or to obtain from cultures of the pathogenic bacillus in a direct or an indirect manner a substance which will cure the disease in the human subject. Hitherto, unfortunately, these efforts have not met with generally recognised success. There is every reason to hope, however, that eventually the much-wished-for result will be accomplished. Dr. Paterson in his investigations starts from the fact that tubercle bacilli can easily be found in the walls of tuberculous abscesses but not in the contents. The organisms may be so few that inoculation experiments may be necessary to demonstrate their presence. As the conditions in the interior of such abscesses are apparently favourable to growth, and yet the bacilli do not increase but actually diminish in numbers, Dr. Paterson argues that there must be some substance in the contents which is inimical to the bacilli; and he further suggests that as the fluids are being constantly renewed presumably this deleterious material is in the encapsulated solids. These deductions are certainly well founded and Dr. Paterson has acted energetically on them. He experienced difficulty in finding a satisfactory process by which the chemical constitution of the solids should be as little changed as possible and yet the living bacilli present be destroyed, but eventually cold applied intermittently appeared to produce the desired result. He proved that if tuberculous pus be kept in a refrigerator for five or six months, but allowed to thaw frequently during that time, the pus would not induce tuberculosis when injected into guinea-pigs. The serum from the pus was then drawn off and the sediment carefully washed so as to remove sound in theory; but they who know the worthy Baronet, who is as innocent of all extra-professional information as Roderick Macleod, will readily acquit him of having ever digressed into a disquisition connected with literature or taste. The fact is, that the passage in question was an interpolation of our reporter, who, in garnishing the worthy Baronet's lecture with this somewhat unjustifiable piece of *fioriture*, little imagined that he was laying a trap to catch a Pure.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances and Administration of the Rural District of Pocklington, *by* Dr. L. W. DARRA MAIR.[1]—Many of the reports lately issued from the medical department of the Local Government Board afford evidence of the unsatisfactory manner in which rural district councils often perform their duties as sanitary authorities. The district of Pocklington in the East Riding of Yorkshire, which includes the town of Market Weighton and a large agricultural area in its vicinity, appears to be no exception to the rule. Sanitary government in this district, or what there is of it, is exercised by a rural district council which consists of 49 members who are also Poor-law guardians. The council meets in intervals of Poor-law business and has no committees for public health or sanitary purposes. The duties of sanitary inspector or inspector of nuisances are intrusted to two surveyors of highways who give nearly all their time to their surveyor's work. These officers Dr. Mair found not to be properly informed of elementary matters affecting the public health of the district; the inspector acting in Market Weighton, for example, was ignorant of the extent to which houses in that town are served by the public water-supply or are dependent on private wells, while the same officer protested against being required to give any assistance to the medical officer of health in dealing with cases of small-pox. The district is divided between two medical officers of health, an arrangement usually unsatisfactory and in this case attended by special drawbacks. Neither of the two surveyor-inspectors has an area corresponding to that of a medical officer, while the effect of the subdivision is that neither medical officer receives sufficient salary to enable him to devote adequate time to the work. The district council's meetings are not attended by either, and the inspectors who do attend are not in a position to give useful advice. It is not surprising in these circumstances that the council, without consulting either medical officer, put up a small-pox hospital which no one could use, or that money spent for "sanitary" purposes has habitually been expended to little advantage. Dr. Mair, in reviewing the situation, concludes that "it will seem to most people, and rightly, in my judgment, that the sanitary administration of this district in its present condition constitutes an actual danger to the inhabitants." He shows that many of the water supplies of the place are unsafe, and that in consequence water-borne outbreaks of enteric fever have occurred from time to time in different localities, most recently in Shipton. "Examination of the records of the council show that during the past few years many samples of drinking water have yielded such bad results on analysis that the analyst has described them in such terms as 'filthy,' or 'enormously' polluted, a 'moderately dilute solution of sewage,' and so forth." Certain villages are in need of a system of public scavenging. Cowsheds are often in great need of supervision, as also is the character of the water used for washing milk utensils. In one instance serious drainage defects were discovered at a cowshed as a result of the occurrence of enteric fever on the adjoining premises. Dr. Mair found three years afterwards that an order of the council to remedy these defects had not been complied with.

On a Re-inspection of the Durham Rural District, *by* Dr. H. TIMBRELL BULSTRODE.[2]—This report relates to an important colliery district which was inspected in 1905 by Dr. R. A. Farrar, who reported to the Local Government Board on its sanitary conditions. As the district council took exception to this report, and disputed some of the statements which it contained, the Local Government Board took a practical, though somewhat unusual, course and sent a second inspector to inquire into the matters in dispute. As a result different parts of Durham rural district have been investigated by a party consisting of two inspectors of the Local Government Board (Dr. Bulstrode and Dr. Farrar), the county medical officer of health (Dr. T. E. Hill), and various members and officers of the district council. Dr. Bulstrode shows that the result of such thorough investigation was to emphasise the importance of the shortcomings of the district which had previously been pointed out. It was satisfactory to find that certain of the defects to which Dr. Farrar drew attention had already been remedied, and after the trouble which has now been taken by the supervising authorities to show this district council what is at fault it may be expected that further and substantial improvement will result. One of the most striking features of colliery districts in the north of England, specially noted by Dr. Bulstrode in the present case, is the contrast in the matter of cleanliness and general well-being between different villages the inhabitants of which are of the same class and occupation and receive the same wages. The character of the house accommodation is the dominant factor in the matter. Hardly less important is the condition of the roads. Where the road outside the dwelling is unmetalled and usually little better than a quagmire, as is too often the case, it can hardly be expected that the collier's wife will take pride in the cleanliness of her house or her children. Untidiness of the inhabitants and prevailing dirt in the road and backyards are prone to be seized upon by property owners—often colliery proprietors—as a reason for doing as little as possible to improve the structural conditions of dwellings or to abate overcrowding. Is it reasonable, they may ask, to expect us to incur expense for people with these habits of life? Moreover, one of these days the mine will be worked out and the cottages will be useless. Again, all colliery districts are liable to subsidence of surface and cracking of house walls in unexpected places and it is better for us to build cheaply and repair as little as may be. In short, there are numerous and plausible arguments with which to persuade the local authority to take "long views" of the situation and do nothing. But in such case the answer of the local authority, as Dr. J. C. McVail has told us in a well-known essay and as Dr. Bulstrode shows by reference to other colliery villages, should be to declare its preference for "short views"; to make up its roads; to get dilapidated houses repaired; to close dwellings unfit for habitation; to cleanse its middens; to put a stop to overcrowding; and generally to be content to do its best to mitigate present evils without troubling unduly about the future.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Manchester.—The estimated population of Manchester at the middle of 1905 was 631,933, the birth-rate for that year was 29·0, and the death-rate was 17·82 per 1000. The infantile death-rate was 164·42 per 1000 births. The general death-rate was much below that formerly recorded; Dr. James Niven points out, however, that Manchester has but shared in the general improvement and that her position amongst the large towns is much the same as usual. Associated with this low Manchester death-rate was the fact that flour and coal were cheaper than in previous years but the price of wheat was unaltered. It is curious that in these circumstances the amount of outdoor relief was much greater in 1904 and 1905 than in previous years, but Dr. Niven, while viewing this with apprehension, thinks that the increased outdoor relief may be partly attributed to a change of policy. Although he evidently regards indiscriminate outdoor relief as eminently undesirable, he suggests that, in cases where through the illness of the bread-winner or from other causes a number of children are without sufficient means of subsistence, an effort should be made to keep the family well nourished until the older children can work. He has approached the Charity Organisation Society as to this point but apparently its funds will only avail for more or less temporary distress. We are entirely in accord with Dr. Niven that "attention to this most pressing need would greatly aid in the diminution of disease, which fastens on neglected and ill-nourished children." He is apparently of opinion that work of this nature should be original casein than it is possible to produce by the employment of high temperatures.

[2] Ibid., No. 237, Price 3d.

THE meeting of the British Medical Association was formally opened in the Convocation Hall of the University of Toronto on Tuesday, August 21st, under the presidency of Dr. R. A. Reeve, dean of the Faculty of Medicine in the University.

MEDICINE AND THE LAW.

Application for Order for Inquisition in Lunacy.

RECENT events have made it necessary for medical *men to* appreciate the details of application for inquisitions in *lunacy. Section 90 of* the Lunacy Act, *1890*, provides that the judge in lunacy may upon application by order direct an inquisition whether a person is of unsound mind and incapable *of managing himself and his affairs.* The petition should be supported by affidavits by medical men—preferably unconnected with lunatic asylums—and by members of the family of the alleged lunatic, and *other* persons who *know him*, not *merely* stating that the *respondent* is of unsound mind, or setting forth in general terms the facts on which the *deponent relies*, but *giving the precise* facts and evidence. It is unnecessary and undesirable that an affidavit in support of a petition should be a *very lengthy document*, *but* the deponent should *state all the material facts on which* his inference of unsoundness of mind is based, and should see that the facts which he *does state* point to unsoundness *of* mind *and incapacity on* the *part* of the alleged lunatic to manage himself and his affairs. The petition for an *order for* an *inquisition* ought generally *to* be preferred by the nearest relative of the alleged *lunatic*, and if it is not *so preferred the* court looks at it with peculiar jealousy, for the fact implies that the persons who ought to protect *him* are *neglecting their duty.* On *the other* hand, no rule has been laid down to discourage proper applications from any quarter, since persons of unsound mind may *require protection* quite as much against their *relatives as* against those *who do not* belong to that class. Thus a commission may issue upon an information by the Attorney-General, *by* an *executor* under a will against a legatee under the same will, by a trustee under a deed against his *cestui que trust*, by a tenant of the supposed lunatic, where there was no doubt that the party was in a state that made him *the proper subject* of the *commission* (this was *done* in a case where action was opposed by the *subject's* mother, under whose care he was residing, while it *was* alleged that the tenant, being in *arrear for* rent, was *taking the* step with a view to gaining time); by a creditor against his debtor; and even by an absolute *stranger.* *Where the* alleged lunatic is within the jurisdiction no order is to be made upon any *petition* until after the expiration of seven clear days from service upon the alleged lunatic of notice of the petition. An inquisition may be ordered when either the person or the property of an alleged lunatic, whether a subject or an alien, and whether of full age or not, is within the jurisdiction. A commission in lunacy may issue *against* an infant, but as the Chancery Division has power over infant wards of court and their estates such a *proceeding* will *be* generally unnecessary, except in particular circumstances when the more ample powers given in lunacy may be required for managing their estates.

A commission may *also issue* against a subject (1) resident out of, but possessing property in, England, and (2) possessing property out of, but resident in, England. In *Ex parte Southcot* (2 Ves. sen. 401) Lord Hardwicke, after a full examination of the principles and practice applicable to the subject, made an order for a commission against an alleged lunatic resident in Flanders *but possessing* property in England, *directing the inquiry* to be held where the mansion and the greater part of the estate lay. This precedent has been repeatedly followed. *Under the Rules* in Lunacy, 1893, r. 1, an inquisition may be ordered in the case of persons incapable by mental infirmity, arising from disease or age, of managing their affairs. *An action* will *lie for maliciously suing out* a commission in lunacy against a person, but to support such an action malice or a want of probable cause must be proved. *If a total want of probable* cause is proved malice may be implied. But although express malice is proved some slight evidence of want of probable cause must be given. The court may, where the lunacy of a person is in question, interpose by making a provisional order for the care and custody of the person and the estate until the *lunacy* is finally determined. If the case is urgent the court will make the appointment upon an *ex parte* application (*Pountain, In re,* 37 Ch. D. 609). But this interference is provisional and arises *ex necessitate* in cases of emergency *and is* only allowed *as* subservient to the inquiry and while it is in progress. The *order of the judge* in lunacy directs the inquisition to be held (1) at or near the place of abode of the alleged lunatic if within the jurisdiction; and (2) *when the alleged* lunatic is not within the jurisdiction at the place in England where his *mansion, house, or other* property is situated. If he have no such property, then at his English residence; if he has no such *residence*, then in the county of Middlesex. This rule regarding *holding* the *inquisition at or* near the place of abode of the alleged lunatic is not, however, inflexible, and it has been occasionally departed *from*, when, e g., there was reason to believe that a *strong local feeling as* to the proceedings existed in the neighbourhood where *the alleged* lunatic resided. The judge in lunacy may make an order to prevent the removal of an alleged *lunatic out of the jurisdiction even before a commission* is issued. But such an order will not be made except upon applicants satisfying the court that the party is a fit *subject* of a commission in lunacy, and *that there* is a reasonable apprehension *of* an intended removal. Whether the inquiry is with or without a jury, and wherever it is held, the proceedings are open to the public. If the medical witnesses for the alleged lunatic see him *alone* the medical witnesses on the other side are entitled to the same opportunity. Section 98 of the Lunacy Acts, 1890-91, enacts that the *inquisition shall be confined to the question* whether or not the alleged lunatic is at the time of the inquisition of unsound mind and incapable of managing himself or his affairs, and *no evidence as to anything done or said by him or* as to his demeanour or state of mind at any time, being more than two years before the time of the inquisition, shall be *receivable in proof of insanity*, or on the trial *of any traverse* of an inquisition, unless the person executing the inquisition otherwise directs. If upon such inquisition it appears that the alleged lunatic is *of unsound* mind, *so* as to be incapable of *managing* his affairs, but that he is capable of managing himself, and is not dangerous to himself or to others, it may be so specially found and certified.

Although the power of *courts of* law to prevent the publication of their proceedings pending *litigation has* been repeatedly affirmed it is now rarely exercised, and fair, accurate, and *bonâ-fide* reports of cases in *any* public court of justice, a *category to which* the Master's Court belongs, are privileged, unless the evidence is obviously unfit for publication. But comments on lunacy *proceedings which are still sub judice* may be punished as contempt and Section 99 of the Lunacy Act gives the Master in Lunacy, while employed in executing an *inquisition, power* to *commit.*

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 23rd, 1828.

RODERICK MACLEOD, in reprinting *the* "Stanzas on Dr. Harrison," the week after *they* appeared in THE LANCET, states, that he would have published them sooner had he not been at the sea-side at the time they were transmitted to *him*, and that they were acknowledged in the *Excrescence* of the 19th of July. On turning to the Excrescence of that date, we find, as we had good reason to anticipate, no such acknowledgment; and the truth of the other part of RODERICK'S statement may be estimated, when we add, *that we* made an alteration, *proprio marte*, in the manuscript of our Correspondent, which alteration *is faithfully* copied in the Excrescence. *This reminds* us of SIMON PURE'S tranquil transcription from the pages of THE LANCET, in his exclusively *genuine* edition of Sir ASTLEY COOPER'S Lectures, of a long passage touching the connexion between literature *and science*, and the reciprocal influence which literary and scientific pursuits were supposed *to* exercise *on* each other. The passage is rather a fanciful one, and not, perhaps, very in the ten preceding weeks from 50 to 865, further rose last week to 1385; the highest annual rates from this disease last week were 8·0 in East Ham, 8·2 in Birmingham, 14·0 in West Ham, and 14·2 in Birkenhead. The largest proportional fatality from measles occurred in Rotherham, Tynemouth, Stockport, Norwich, and Huddersfield; and from whooping cough in Walsall and Swansea. Of the 50 deaths from diphtheria 15 occurred in London, eight in Manchester and in Salford, three in Portsmouth, and three in Bradford. The 25 fatal cases of scarlet fever included eight in London, four in Manchester, and two in Birmingham. Three deaths were referred to "fever" in Portsmouth and four in London. No case of small-pox was under treatment in the Metropolitan Asylums hospitals during the week, no case having been admitted since the end of June. The number of scarlet fever cases under treatment in the Metropolitan Asylums hospitals and in the London Fever Hospital, which had been 3120 and 3051 at the end of the two preceding weeks, further declined to 3046 on Saturday, August 18th; 317 new cases were admitted to these hospitals during the week under notice, against 415 and 308 in the two preceding weeks. The deaths referred to *pneumonia* and other diseases of the respiratory organs in London, which had been 101, 111, and 112 in the three preceding weeks, further rose to 119 last week, but were 19 below the corrected average in the corresponding week of the four preceding years, 1902–05. The causes of 39, or 0·8 per cent., of the deaths registered in the 76 towns during the week under notice were not certified either by a *registered medical* practitioner or by a coroner. All the causes of death were duly certified in London and in 53 other of the 76 towns; the proportion of uncertified causes of death showed, however, a considerable excess in Gateshead, Sunderland, South Shields, and Wigan.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 11·8 and 14·0, per 1000 in the two preceding weeks, further rose to 14·4 during the week ending August 18th but was 2·6 below the mean rate in the same week in the 76 English towns. The rates in the eight Scotch towns ranged from 10·7 in Leith and 11·8 in Greenock to 19·2 in Paisley and 19·6 in Perth. The 492 deaths in the eight towns exceeded the number in the previous week by 11, and included 37 which were referred to diarrhœa, 11 to whooping-cough, four to measles, four to diphtheria, four to "fever," one to scarlet fever, and not one to small-pox. In all 61 deaths resulted from these principal epidemic diseases in the week under notice, against 50 and 64 in the two preceding weeks; they were equal to an annual rate of 1·8 per 1000, which was no less than 3·5 below the rate from the same diseases in the 76 English towns. The deaths attributed to diarrhœa in the Scotch towns, which had steadily increased in the four preceding weeks from 11 to 34, further rose last week to 37, of which 18 occurred in Glasgow, seven in Dundee, five in Paisley, and three in Edinburgh and in Aberdeen. Seven of the 11 fatal cases of whooping-cough were returned in Glasgow and two in Aberdeen, in which latter town two of the four deaths from measles also occurred. The four deaths referred to "fever" included three in Glasgow (all of which were certified as cerebro-spinal meningitis) and one in Perth. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 52, 61, and 68 in the three previous weeks, were again 68 last week, and exceeded by 28 the low number returned in the corresponding week of last year. The causes of 11, or 2·2 per cent., of the deaths registered during the week were not certified; the proportion of uncertified deaths in the English towns did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 16·8 and 17·3 per 1000 in the two preceding weeks, further rose to 19·7 during the week ending August 18th. During the first seven weeks of the current quarter the death rate in the city averaged 18·6 per 1000, the death-rates during the same period being 13·4 in London and 12·9 in Edinburgh. The 143 deaths of Dublin residents during the week under notice showed a further increase of 17 upon the numbers returned in the two preceding weeks, and included 29 which were referred to diarrhœa, one each to measles, whooping-cough, and "fever," and not one either to small-pox, scarlet fever, or diphtheria. These 32 deaths from the principal epidemic diseases showed a further increase of 13 upon recent weekly numbers and were equal to an annual rate of 4·4 per 1000, the death-rate last week from the same diseases being 5·4 in London and 0·9 in Edinburgh. The 29 fatal cases of diarrhœa in Dublin showed an increase of 19 upon the number in the previous week, whereas the fatality of other epidemic diseases showed a marked decline. The deaths both of infants and of elderly persons considerably exceeded the numbers in recent weeks. Three inquest cases and two deaths from violence were registered; and 38 per cent. of the deaths occurred in public institutions. The causes of all the deaths registered during the week, except one, were duly certified by a registered medical practitioner or by a coroner, and the causes of all the deaths in London and in Edinburgh were duly certified.

THE SERVICES.

Royal Navy Medical Service.

The following appointments are notified:—Fleet Surgeons: H. W. G. Doyne to the *Bulwark* and G. T. C. Collingwood to the *President*, for London recruiting headquarters; C. C. Woodwright to Portland Hospital; and G. A. S. Bell to the *Irresistible*. Staff Surgeons: Y. D. S. Milln to the *Proserpine*, and on recommissioning. *Surgeons:* R. S. Osborne to the *Merlin*, on commissioning; W. L. Hawkins to the *Leda*, on recommissioning; J. R. Muir to the *President*, for three months' study at Dreadnought Hospital, Greenwich; and G. S. Davidge to the *President*, for three months' study at West London Hospital.

Royal Army Medical Corps.

Lieutenant-Colonel T. H. Corkery, retired list, is appointed to the medical charge of the troops at Exeter, and Major A. R. Aldridge is appointed Sanitary Officer at the Indian Army Headquarters.

Indian Medical Service.

The King has approved of the following promotion made by the Government of India:—*Madras:* To be Colonel: Lieutenant-Colonel William O'Hara (dated May 28th, 1906).

The King has also approved of the retirement from the service of the undermentioned officer: Lieutenant-Colonel David Prain, C.I.E. (dated July 31st, 1906).

Volunteer Corps.

Rifle: 2nd (Berwickshire) Volunteer Battalion (the King's Own Scottish Borderers): David Robert Taylor (formerly Lieutenant) to be Surgeon-Lieutenant (dated August 18th, 1906). 1st (Ross Highland) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Lieutenant R. Brodie to be Surgeon-Captain (dated August 18th, 1906).

Royal Army Medical Corps (Volunteers).

Eastern Command: Maidstone Companies: Joseph Ward to be Lieutenant (dated August 1st, 1906). Bedford Bearer Company: Lieutenant C. H. Perram to be Captain (dated August 18th, 1906). Sussex and Kent Bearer Company: Major J. Turton (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Sussex and Kent Volunteer Infantry Brigade) to be Lieutenant-Colonel (dated August 18th, 1906).

Royal Hospital, Chelsea.

Lieutenant-Colonel R. W. Ford, D.S.O., R.A.M.C., having completed five years' service as deputy surgeon of the Royal Hospital, Chelsea, leaves that establishment and is succeeded by Lieutenant-Colonel R. J. C. Cottell, who served in South Africa in 1899 to 1902. Colonel Ford is under orders for Gibraltar.

Enteric Fever in India.

The Government of India has sanctioned the formation of a standing committee for the purpose of investigating and advising on enteric fever in India and its prophylaxis. The undermentioned officers, nominated by the Commander-in-Chief, have been appointed to the committee:—*President:* Surgeon-General W. L. Gubbins, principal medical officer of His Majesty's forces in India; *Vice-President:* Surgeon-General A. Scott Reid, principal medical officer of the Northern Command; *Members:* Colonel R. H. Forman, done by private charity rather than by official outdoor relief, but possibly something approaching the Elberfeld system of relief, where the money is dispensed by unpaid visitors who are responsible for an economical and productive disposal of the poor-rate funds, might best meet the requirements of these cases. 24 per cent. of all the deaths in Manchester occur in its public institutions, and Dr. Niven thinks that possibly the maintenance of this high percentage represents a diminished aversion on the part of the poor to seek admission to the union hospitals.

An increase in the prevalence of diphtheria is taking place in Manchester at the present time, and the medical officer of health is consequently devoting more attention to the subject of its causation and control. During the year a circular was addressed to the medical practitioners urging them, in dealing with suspicious cases, at once to inject antitoxin and not to wait until their suspicions are confirmed by the bacteriologist; both the syringes and the antitoxin are at the disposal of medical practitioners on application at the town hall. "If," says Dr. Niven, "we could by sufficient promptitude in treatment avert the fatal issue of diphtheria we should be fulfilling one of the aims of the Public Health Act"; and he considers that it is difficult to see how a medical man can be relieved of responsibility if he fails to save a child under his care suffering from diphtheria, assuming that the fatal issue can be averted by injection of a sufficient amount of antitoxin within the first three days. So strongly does Dr. Niven feel upon this point that during recent months letters have been sent to practitioners when it has been doubtful whether antitoxin has been used. This attitude on the part of a medical officer of health raises some novel and interesting issues and we may add that we are far from antagonistic to the attitude adopted, though it indicates an individualistic tendency on the part of the public health authorities. It is pointed out in the report before us that diphtheria is largely spread by "carrier" and unrecognised cases in schools and elsewhere, and the medical officer of health remarks, "All these are conditions which a sanitary inspector cannot be expected to ascertain or to deal with; yet to discover them and prevent them from remaining sources of danger is the essence of the prevention of diphtheria"; and he then pleads both with respect to diphtheria and scarlet fever for the services of a "medical investigator," who would be able to undertake the requisite investigation rapidly and to administer preventive doses of antitoxin when requisite. In Dr. Niven's view "the power of isolation in hospital to limit the spread or fatality of scarlet fever and diphtheria is but limited and more preventive value could be got, in my opinion, by increasing the staff of the medical officer of health." As regards diphtheria "contacts," he adds: "As for the wholesale isolation of contacts I do not believe it to be practicable here and I am not clear that it is desirable."

Much work was done in 1905 on the investigation of enteric fever, a disease which, falling mainly on those at ages from 10 to 45 years, is of considerable economic importance. The conclusions of the investigators are to the effect that the disease is spread in Manchester largely by failure to recognise the disease, especially in the case of children; its infective power is "fairly high and this is also particularly obvious in children." In the prevention of the disease skilled inquiry by trained health officers is likely to produce the greatest results at a minimum cost, and Dr. Niven is careful to point out that the best results are not to be obtained by the ordinary routine methods of the sanitary inspectors, useful as they may be. Shell-fish have, we are told, a decided influence in maintaining the prevalence of enteric fever and diarrhœa in Manchester, and in order that cases thus caused can be properly investigated further powers are necessary for procuring information with reference to the sources of the infected shell-fish. Mussels not properly cooked should not, in his opinion, be used as an article of food. He thinks, too, that probably flies play a part in the spread of enteric fever in August and September, and that therefore steps should be taken towards the destruction of the house-fly and its eggs. Dr. Niven has evidently, like others, found considerable difficulty in procuring from the wholesale shell-fish merchants the names of the "layings" from which supplies of shell-fish were furnished to retail dealers involved in the sale of suspected mussels. He has, however, obtained sufficient information to raise suspicion against certain layings on the Welsh and Irish coasts, and he adds that he will not be satisfied of their freedom from pollution without examination either by himself or by the Local Government Board. Curiously enough, Dr. Niven makes no reference to any Dutch mussels, but whether this is because none of these imported molluscs are consumed or because none have come under suspicion is not clear. Certainly a large number of mussels are imported into this country from Holland. We are quite in agreement with Dr. Niven that the local authority should be in a position to obtain the name of any laying or natural gathering ground from which any given mussels have been procured, and that shell-fish hawkers should be duly registered. Provisions such as these should be embodied in any fresh Public Health Bill unless in the meantime Manchester can secure such powers for herself by means of a local Act. But possibly the shortest way of bringing about amendment of the law as regards shell fish generally would be to urge the Local Government Board to promote legislation on the lines recommended by the Royal Commission on Sewage Disposal. Dr. Niven is clearly in need of further professional assistance to enable him to carry on the admirable investigations which he has in hand and in contemplation, and every medical officer of health who is at the same time an epidemiologist will agree that no sanitary inspector can bring to bear upon these etiological investigations the knowledge necessary to enable their full value to be brought out. It is to be hoped that the future will see a very considerable increase in the number of assistant medical officers of health throughout the country.

A capital summary of the measures taken in Manchester towards the better control of tuberculosis is furnished in the report, and with regard to the system of voluntary notification Dr. Niven makes the following somewhat significant remarks: "It has been believed by many that a scheme of notification would fail unless there were a hospital to which cases might be sent by the authority dealing with notification. This is not the case. But there is more in this view than I had at first supposed. Even supposing Bowdon Hospital and the Hardman-street out-patient department had not been in existence it would still have been advisable to begin with a notification scheme so that the needs of the community might be ascertained and much useful work would have been done by way of instruction. But it has to be remembered that to sustain household visits month after month, perhaps for years, becomes rather trying and demands great tact and management from the visitor as well as judgment on the part of the person visited." But Dr. Niven is inclined to believe that the death-rate from pulmonary tuberculosis is beginning to show a result from the work which has been done in consequence of notification since 1899, and all who know Dr. Niven and his work will trust that his hopes may be realised.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8877 births and 5157 deaths were registered during the week ending August 18th. The annual rate of mortality in these towns, which had steadily increased in the five preceding weeks from 11·7 to 14·6 per 1000, further rose to 17·0 in the week under notice. During the first seven weeks of the current quarter the death-rate in these towns averaged 13·4 per 1000, the same rate having also prevailed in London. The lowest death-rates in the 76 towns last week were 6·5 in Handsworth, 6·6 in Hornsey, 7·2 in King's Norton, and 7·3 in Devonport; the rates in the other towns ranged upwards to 26·0 in Tynemouth, 26·1 in Middlesbrough, 26·8 in Wigan, and 28·9 in Birkenhead. The 5157 deaths in the 76 towns showed a further increase of 733 upon the numbers returned in recent weeks, and included 1623 which were referred to the principal epidemic diseases, against numbers increasing from 361 to 1105 in the five preceding weeks; of these no fewer than 1385 resulted from diarrhœa, 103 from measles, 50 from diphtheria, 42 from whooping-cough, 25 from scarlet fever, 18 from "fever" (principally enteric) and not one from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 5·3 per 1000 in the 76 towns and to 5·4 in London. No death from any of these epidemic diseases was registered last week in Bournemouth, Reading, Halifax, or Stockton-on-Tees; whereas they caused annual death-rates equal to 11·9 per 1000 in Norwich and Leyton, 15·0 in West Ham, and 16·0 in Birkenhead. The deaths referred to diarrhœa, which had steadily increased

Ten weeks ago I was called to see a young lady pupil teacher in a school of 18 young girls. She had arrived at the school 48 hours before I saw her and had well-marked mumps. During this 48 hours she had been in close association with the girls during the daytime and had slept in the same dormitory for two nights with several of them. None of the girls had ever had mumps as far as I could ascertain. The torch and the magazine were therefore thoroughly introduced to each other. Instead of waiting for the almost inevitable explosion to follow (a course, I fear, that I have pursued before now), with the help of the head mistress I instituted a regular drill twice daily, which consisted in each girl thoroughly washing out her mouth and gargling with an antiseptic lotion under direct supervision. This was kept up for a fortnight and no case of mumps occurred in the school. I claim no originality for this idea, which has probably suggested itself ere now to many others, but I intend to try some similar plan in my next household that shall have a case of scarlet fever. The specific organism in each disease probably takes some hours to reach a site where it can comfortably grow and multiply and our endeavours should be directed to slaying it or them before they get safely located.

I am, Sirs, yours faithfully,

Caterham Valley, August 20th, 1906. W. BLIGH, M.D. Lond.

ANALYSIS OF SUSPECTED FOODSTUFFS.

To the Editors of THE LANCET.

SIRS,—A patient of mine after eating certain brown bread was taken with violent pain and vomiting, and her mother also was sick on eating the bread. A sample of it was brought to me and showed minute blue specks all over and through its substance. I sent some to the medical officer of health of the district where my patient lived and he, although he sent some on to the county analyst, affirmed himself in no way responsible for its analysis. The Maidstone analysts declined to examine the substance, although the Home Office referred me to them. Now what am I to do? Are the public to be semi-poisoned and no one to be responsible for an inquiry into the cause? I offered the usual fee for its analysis in vain, yet I fail to see why the medical man (to whom the complaint is generally made) should bear the cost of tracing the cause of such trouble. The baker from whom came the bread had promptly returned the flour to the millers and would not or could not give any information. Trusting that one of your numerous readers may enlighten me as to the law on the point,

I am, Sirs, yours faithfully,

Penge, S.E., August 18th, 1906. HERBERT GREENWOOD.

BULLET EXTRACTED AFTER BEING 42 YEARS IN THE BODY.

To the Editors of THE LANCET.

SIRS,—Some time ago I was asked to attend a man for a swelling in the calf of his leg, which prevented him walking. On examination the swelling appeared to be in connexion with a hard foreign body situated deep down in the tissues. I made an incision into this mass of inflamed substance and dissected out a flattened bullet. The patient was a pensioner and formerly belonged to the Royal Marines. He received a shot in his hip during an action off the West Coast of Africa while serving on board H.M.S. *Madagascar*. He was in consequence invalided home and for 42 years this bullet had gradually worked its way from the hip to the calf, where it was extracted owing to the irritation it produced.

I am, Sirs, yours faithfully,

Ealing, W., August 22nd, 1906. EDWIN CHILL, M.D. Edin.

WHAT IS A SPECIALIST?

To the Editors of THE LANCET.

SIRS,—The discussion about "specialists" has been most opportunely started by "A. Z." in THE LANCET of July 28th, p. 253. I have always failed to see why it should be considered unprofessional for a medical practitioner to intimate on his door-plate, bills, &c., the fact that he practises a special branch of his profession, to which he has devoted special time and energy. And this the more as I am fully aware that the present system of unavoidably coupling specialisation with hospital appointment is not only a hindrance to the bringing out of what is best in our young and talented practitioners but is also a means of foisting on the public many men as specialists who have often nothing more "special" about them than their attachment to a hospital. The letter of "F.R.C.S. Eng., M.D." in THE LANCET of August 18th, p. 463, brings out that very forcibly and whoever has worked within the walls of a hospital will doubtless have met such instances as he has mentioned.

As the system stands at present it is only the fortunate few, who have managed to catch a timely connexion with a hospital, who are recognised and known as specialists. The public in order to find a specialist can only turn either to the lists of the hospital staffs or to the private practitioner who has generally no better information to give, especially if he chances to be a stranger in the town in which he practises. And, furthermore, why, I ask, is the specialist to be prevented from proclaiming openly to the public what everybody takes for granted? Why is he to be dependent on the goodwill of his fellow-practitioners to recommend and send patients to him?

In Germany and Austria (of both of which I have experience) it is a common custom for the general practitioner to indicate on his door-plate that besides being a "practischer arzt" (general practitioner) he has made a "specialität" (speciality) his own, a fact which does not seem to affect the status of the "real specialist" who comes in for his share of legitimate work. There, indeed, the latter is the specialist κατ' ἐξοχήν, because in the earlier stages of specialisation he has the competition of the general practitioner, and it is only when he has attained eminence in his branch (which eminence varies according to the standard of the town) that he is looked upon as differing from the general practitioner.

I think a good deal of mere conservatism clings to our profession and an imaginary standard of honour results. Surely it is no advertisement, but the mere open statement of an understood fact, that a man who has specialised (if we recognise specialisation at all) intimates this to his friends, patients, and would-be patients. I for one should be glad to see this done—the sooner the better.

I am, Sirs, yours faithfully,

August 21st, 1906. S. H.

VITALITY OF THE EXCISED MAMMALIAN HEART.

To the Editors of THE LANCET.

SIRS,—I was recently a passenger in a train when about 40 miles from London a woman was run over. Her body was divided into two across the thorax and nearly the whole heart—the ventricles and portions of the auricles—had somehow been jerked out and lay quite apart. The ventricles were still making irregular but definite contractions, exactly like those which may be seen in the heart of a frog after prolonged exposure. It was at least a minute, and I think possibly two minutes or more, after the injury was inflicted before I was in a position to make this observation and the movements had apparently ceased in another minute or two when I had to re-enter the train. Possibly it is not generally known that the mammalian heart may so clearly exhibit its powers of independent action. In any case the opportunity of observing such muscular contractions in the human heart must arise very rarely.

I am, Sirs, yours faithfully,

August 17th, 1906. F.R.C.S. EDIN.

ROYAL CORNWALL INFIRMARY, TRURO.—The annual meeting of the subscribers to this institution was held on August 13th under the presidency of the Hon. John Boscawen. The medical report stated that during the past year 473 in-patients had been admitted, against 476 in the previous 12 months. 1165 out-patients had been treated, compared with 1003 in the preceding year. The annual cost per bed was £57 6*s*. In 1905 Sir Robert Harvey gave £1000 for endowing a bed to the memory of the late Lady Harvey and in January, 1906, he gave a similar sum for endowing a bed in memory of his late son. The financial statement showed that the expenditure exceeded the income by £195 and the committee state in the report that unless the deficiency is met one of the wards must be closed. The report of the committee of the Perranporth Convalescent Home for Men (founded and endowed by Mr. Passmore Edwards) stated that 114 patients had been admitted during the year and the financial statement was satisfactory.

principal medical officer of the Bombay Brigade; Lieutenant-Colonel T. P. Woodhouse, Captain L. W. Harrison, Captain E. B. Knox (secretary), Captain A. B. Smallman, and Lieutenant E. J. H. Luxmoore, Royal Army Medical Corps. Nominated by the Home Department:—Members: Lieutenant-Colonel J. T. W. Leslie, Sanitary Commissioner with the Government; Lieutenant-Colonel D. Semple, Director of the Central Research Institute; Major G. Lamb and Captain E. D. W. Greig, I.M.S. Lord Kitchener presided on July 31st at Simla over the first meeting of the committee and gave a long and interesting address in which he set forth the aim and object with which the committee had been constituted and briefly outlined the work which lay before it. The Commander-in-Chief in his address passed in review the great advances which had been made and not only showed that he had been uncommonly well posted up in this respect but that he was able, from his own point of view, to make some practical and suggestive remarks on the subject and practice of anti-typhoid inoculation.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The number of this journal for the present month is a good one. Lieutenant-Colonel A. M. Davies, R.A.M.C., continues his papers on the reports of the Commission for the Investigation of Mediterranean Fever and deals with various points connected with the sanitary condition of the barracks in Malta under the general headings of situation, construction, water-supply, and drainage. There are also contributions on the Health of the Soldier, with Special Reference to Preventable Diseases, by Lieutenant-Colonel H. J. Barratt, R.A.M.C., one of a descriptive and practical nature by Major P. G. Ievers, R A.M.C., on Rider's Sprain, and Colonel David Bruce, R.A.M.C., C.B., F.R.S., deals with South African Stock Diseases. The Removal of Wounded in Hill Warfare, by Captain W. W. Jeudwine, I.M.S., gives an account of a method recently practised by the 30th Punjab Infantry. It is needless to say that the removal of wounded men in Indian mountain warfare is often attended with extreme difficulty. The Inspection of Tinned Foods, by Major W. W. O. Beveridge, D.S.O., R.A.M.C., is mainly based upon experience acquired in the South African War. There are besides the foregoing several other papers of a scientific, bacteriological, or clinical nature.

Correspondence.

"Audi alteram partem."

GOATS' MILK FOR INFANTS.

To the Editors of THE LANCET.

SIRS,—In the *Daily Telegraph* of August 15th the following report appears:—

> Yesterday at the Battersea coroner's court Mr. John Troutbeck held an inquest on the body of Tomasso Cammindillo, aged seven months, son of an ice-cream vendor, living in Sheepcote-lane, Battersea. The coroner interpreted the evidence which was given in Italian. It appeared that the child, which weighed only a little over four pounds, had been fed for six months on goats' milk, and the father explained that he resorted to this because he considered it lighter than cows' milk. Dr. Freyberger said death was due to malnutrition. Goats' milk was worse than skimmed milk and did not contain sufficient fat or sugar. A verdict of death from natural causes was recorded.

It would be interesting to know where Dr. Freyberger obtained the analysis which enabled him to state on oath that "goats' milk was worse than skimmed milk and did not contain sufficient fat or sugar."

Turning to Stevenson and Murphy's "Treatise on Hygiene and Public Health" I find the percentage constituents of the human, cows', and goats' milk given as follows:—

—	Total solids.	Proteids.	Fats.	Milk sugar.	Salts.	Water.
Human	12·59	2·29	3·78	6·21	0·31	87·41
Cows'	12·83	3·55	3·69	4·88	0·71	87·17
Goats'	14·29	4·23	4·73	4·46	0·76	85·71

Whereas the composition of skimmed milk is given as: proteids, 4·03; sugar, 4·04; fat, 1·09; and water, 90·12 (vol. i., pp. 427 and 436). On reference to Pavy's "Treatise on Food," second edition, p. 185, we find the statement that:—

> The milk of the cow ...... the most closely approximates to that of woman but is rather more highly charged with each kind of solid constituent. Next follows the milk of the goat which taken altogether is again rather richer.

These references are, I think, quite sufficient to prove what I had hitherto believed was a matter of common knowledge—namely, that goats' milk is rich in all the constituents of a perfect food and not to be compared with skimmed milk as a form of nourishment. That it is also a useful food for children is shown by the following extract from Dr. Eustace Smith's classical book on "The Wasting Diseases of Infants and Children" (sixth edition, pp. 43, 44).

> With some children, in spite of all possible precautions, cows' milk, however carefully it may be prepared and administered, cannot be digested. ...... In such cases, if there are objections to a wet nurse, recourse must be had to the milk of some other animal, and preference should be given to a milk which *contains* a smaller proportion of casein than that found in the milk of the cow, such as goats' or asses' milk.

The milk, it is true, has an unpleasant smell, but the sense of smell is not well developed in children (Holt's "Diseases of Children," p. 27) and infants do not appear to mind the disagreeable odour. Dr. Freyberger might have gathered from the many papers on Malta fever which have appeared during the past few months that in Malta the *only* milk available is goats' milk. I can only hope that Dr. Freyberger's evidence is incorrectly or imperfectly reported.

I am, Sirs, yours faithfully,
R. J. BLACKHAM, D.P.H. R C.P.S. Lond.,
Captain, R.A.M.C.
August 20th, 1906.

*** We refer to this question in an annnotation.—ED. L.

THE POSSIBLE IMPORTANCE OF EARTH-WORMS AS A FACTOR IN THE SPREAD OF DISEASE.

To the Editors of THE LANCET.

SIRS,—In an article under the above heading which appeared in your issue of July 28th, Dr. Charles F. Fraser describes certain parasitic nematodes found both in the alimentary canal and encysted in the tissue of the common earth-worm *Allolobophora*. The descriptions and drawings that he gives do not permit of the identification of this nematode but it is most probably *Pelodera pellio* A. Schneider. Schneider points out that the larvæ of this species live encysted in the body cavity of earth-worms and are especially numerous in or on the septa. The adults live in damp earth or rotten substances. Another nematode parasitic in the earth-worm is *Ascaris* sp., described by Leuckart, whose second host is probably the mole and possibly also certain carnivorous birds. A third species, named *Discelis filaria* Dujardin, appears to have occurred but once in earth-worms at Paris; although sought for it has not been found again. Finally, we have a fourth nematode, *Spiroptera turdi* Molin, which infests earth-worms. The larva of this parasite is common in earth-worms in Central Europe. It is only found in the ventral vessel but throughout its entire length. The adult form occurs in the various species of *Turdus*, the redwing, the blackbird, song-thrush, and also in the starling. A fuller account of the round worms parasitic in earth-worms will be found in my paper "On the Nematodes Parasitic in the Earth-worm," in the *Archives de Parasitologie*, Vol. VI., 1902, p. 619.

I am, Sirs, yours faithfully,
A. E. SHIPLEY.

Christ's College, Cambridge, August 15th, 1906.

THE PROPHYLAXIS OF MUMPS.

To the Editors of THE LANCET.

SIRS,—When we medical men are called into a household one of whose members is found to be suffering from some contagious malady we are, I fear, usually content with carefully shutting the stable door after the horse has escaped. In other words, we isolate the one sufferer and go away leaving the others to take their chance, with the practical certainty that at the end of the incubation period one or more other members of the household will become ill with the same disease. That this need not always be the case the following instance exemplifies, though of course it cannot be held to absolutely prove anything the technical point of view it is surprising how well this old building has been adapted and rendered healthy by through ventilation and the piercing of numerous windows into the antique walls. Here there are paying wards where strangers taken ill at Lisbon may obtain better nursing than would be possible in a hotel. But if the main part of the building is old, there are several annexes that are quite modern. This is notably the case with regard to the laboratory for clinical analyses, for the application of the Roentgen rays, and for the Finsen system of treatment. For all these purposes a special pavilion has been built in the gardens and is under the direction of Dr. Azevedo Neves who was one of the secretaries of the International Congress of Medicine.

As especially typical of the progress being accomplished in Portugal the Institute of Hygiene should be mentioned. It is beautifully situated on high ground commanding a magnificent view of the Tagus and the port of Lisbon. Here hygiene is taught, notably by the inspector-general of the sanitary services, Professor Ricardo Jorge. The object is to instruct medical practitioners and civil engineers, so that they may obtain diplomas in public health questions. This diploma is now necessary before they can be nominated to a post in the administration of any of the sanitary services. There is here a small but very practical museum where various methods of domestic drainage can be studied with working models. Many systems of ventilation and other kindred subjects are at the disposal of students. Then there are chemical laboratories. Here some 40 samples of milk are analysed every day, together with cheese and other alimentary substances. A good deal of adulteration has been detected at the Institute of Hygiene and this work also serves the purpose of demonstration and teaching.

In the application of these lessons to actual life it is necessary to remember that this Institute of Hygiene was only created by a law enacted on Dec. 24th, 1900. It was the direct outcome of the alarm caused by the several cases of plague that had occurred at Oporto. There has not been much time for the courses of instruction and the diplomas in hygiene now given to affect the general population. Indeed, I was not favourably impressed when taken to see some cheap dwellings where four very small rooms may be rented for about 12*s.* a month. In English towns this would be a very low rent, but in Portugal the wages earned are also very low. It is calculated that each square metre of construction cost £2 2*s.* 5*d.* The company which has built some 45 such cheap dwellings has paid its shareholders 4 and 4½ per cent. interest. More interesting than these dwellings are the 12 asylums situated in different parts of Lisbon to receive, during the day time, children who are abandoned or cannot remain at home because their parents are at work. Here these children are fed, given primary instruction and also are instructed in some manual work. Altogether some 2000 children are thus cared for every day at Lisbon.

Another admirable institution is an adaptation of the French *goutte de lait.* Here are model stables with 16 milch cows. Poor mothers come and are advised as to their infant children and the diet they, as mothers, should take; for every effort is made to encourage mothers to suckle their own children. When necessary suitable food for this purpose is given to them. When they are really unable to suckle their own children, and at the period of weaning, sterilised milk is given and this is obtained fresh from the cows on the premises. There are here a clinique for children's ailments and four *couveuses* for prematurely born infants. Though the *couveuses* were bought two years ago they have not often been utilised. Some hundred infants are taken to this place every day. Modern appliances and machinery are used to wash and sterilise the bottles. Each mother receives eight bottles that can hold a quarter of a litre. The milk costs about 2*d.* per litre. Every two months the cows are tested with tuberculin so as to make quite sure that the milk is trustworthy. The straw given to the cows is removed three times a day and the stables are very lofty and airy. Two women sleep on the premises so as to be up betimes in the morning and have the food ready prepared for the infants at the earliest hour. Careful records as to the weight and size of the children are kept and thus useful statistics are beginning to accumulate. The rooms where the parents and children have to wait are lofty and many windows provide an abundance of light and air. This is an institute that English tourists should visit, for there are not many establishments of this sort in England. The local authorities of Battersea, Bradford, St. Helens, Liverpool, and some other places have organised depôts for the sale of sterilised milk to feed infants, but there is not the same care taken in regard to the mothers or the same clinical advantages as are given at Lisbon.

For the amelioration of the food-supply there is at Lisbon a coöperative bakery which had a turnover amounting last year to £20,000. There are 3444 shareholders and each share is worth £10. They sell the bread at the ordinary price of 4*d.* the kilogramme but there is a 3 per cent. bonus on the purchases besides the interest on the capital. More than 17,000 loaves are baked per day. But the bread is kneaded by hand and baked in ovens warmed by burning wood inside. There is nothing modern or even ingenious about this. When the Lisbon coöperative bakery is compared with the marvellous coöperative bakeries dotted about all over Belgium, and especially the parent institutions of Ghent and Brussels, it will be seen that in this respect the Portuguese have still a great deal to learn. Nevertheless, taken altogether, it is very evident that the Portuguese are endeavouring to move forward. In many different directions beneficent institutions have been established that contribute to the social welfare and progress of the people.

THE OUTBREAKS OF PLAGUE IN JEDDAH AND TREBIZOND.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

THE first news of the appearance of plague in Jeddah was received in Constantinople on May 31st. It seems from subsequent reports that the earliest case was seen on the evening of May 29th. The patient was an Abyssinian, aged 30 years, living in a house in the Sabban "hosh." A "hosh" is a collection of buildings around a courtyard, some of which are almost invariably used as stores for all kinds of goods and others as dwelling-places. This patient had been ill for seven days; he was, when seen, comatose and presented three buboes, one in the groin and two large ones in the neck. He was removed to the municipal hospital on May 30th and on the same day a second case was discovered. A microscopical examination of the contents of one of the buboes in the first case was made and it was found that large numbers of bacilli, resembling morphologically the plague bacillus, were present. On May 31st a third case was discovered in the morning; a little later the bodies of two other persons, apparently dead of the disease, were found, and towards evening three more cases were reported, one of which had been found dead. There had thus been eight cases with four deaths up to the evening of May 31st. On June 1st an extraordinary meeting of the Constantinople Board of Health was held and it was decided to impose five days' quarantine, together with disinfection, and application of the regulations for rat destruction, upon arrivals from Jeddah. Special measures were imposed upon *sambouks* (native coasting vessels) leaving that port. Orders were sent to evacuate and to disinfect the rice store, in which it was reported the earliest patients had been employed. It was said that rice from India had been stored in this depôt and some suspicion attached to this rice as having been possibly the means of importing the infection, either in the rice itself or by means of infected rats. It is noteworthy, however, that no dead or plague-infected rats have been found at Jeddah during the course of the outbreak. Instructions were also sent to isolate the sick and those who had been in contact with them, to disinfect thoroughly the houses they had occupied, and to improve as far as possible the sanitary state of the town of Jeddah. The further course of the outbreak has been as follows:—

From May 29th to June 3rd	...	13 cases,	7 deaths.
,, June 4th ,, ,, 10th	...	8	9
,, ,, 11th ,, ,, 17th	...	7 ,,	7 ,,
,, ,, 18th ,, ,, 24th	...	11 ,,	12 ,,
,, ,, 25th ,, July 1st	...	3 ,,	7 ,,
,, July 2nd ,, ,, 8th	...	5 ,,	5 ,,
,, ,, 9th ,, ,, 15th	...	9 ,,	9 ,,

THE MEDICAL AND HYGIENIC ASPECTS OF LISBON.

DISINFECTION AND NOTIFICATION FOR TUBERCULOSIS.—THE ISOLATION HOSPITALS.—THE LARGEST HOSPITAL.—THE INSTITUTION AND DIPLOMA OF HYGIENE.—CHEAP DWELLINGS.—ABANDONED CHILDREN.—MOTHER'S MILK.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE Fifteenth International Congress of Medicine meeting at Lisbon this year has undoubtedly helped to make known to the British tourist and traveller that Portugal is at once an accessible and interesting country. On inquiry I find that more passages than usual have been booked for Lisbon this summer. For instance, almost every berth on the last two Booth line steamers sailing from Liverpool and Havre for Oporto, Lisbon, and Madeira, was taken. This is the more remarkable as it is not the best time of the year; Portugal is more pleasant in the late autumn and early spring. However this may be, the fact that the tide of tourists is already beginning to flow in that direction recalls to my mind that I have not yet completed the description of the many interesting institutions I visited while in Portugal for the International Congress of Medicine. Among other things and as a matter which directly affects tourists, I did not describe the means taken for isolation and disinfection at Lisbon. The fear of contracting some infectious or contagious fever has deterred many British tourists from going to the continent. This was justified by the fact that there were many places where the necessary precautions were not enforced. Now, on the contrary, not only is such neglect exceptional but in many localities better measures are adopted than those in vogue in England. For instance, in Portugal, according to a law which dates as far back as 1868, the notification of infectious diseases is rendered obligatory. Disinfection is now practised in all cases of typhus fever, typhoid fever, scarlet fever, diphtheria, cerebro-spinal meningitis, plague, cholera, yellow fever, and even for tuberculosis. It was on August 30th, 1902, that tuberculosis was added to the list. In notifying tuberculosis the medical attendant must not only describe the case but also state what measures he thinks are necessary. Indeed, the whole of the scheme for dealing with this disease is so radical that nothing short of an economic revolution could render its strict application possible. For instance, a fine of 4000 reis is inflicted on agencies, offices, and information bureaux recommending or introducing domestic servants unless they can produce a medical certificate not more than three months old which declares that the applicant for employment has been vaccinated, and is not suffering from tuberculosis or other contagious disease. It appears that this rule is carried out fairly well at Lisbon, at any rate in regard to domestic servants and also as to journeymen bakers.

The principle, however, that no one suffering from pulmonary tuberculosis should be allowed in a workshop, factory, mill, or any other place of employment where he might possibly contaminate healthy fellow-workers, though advisable from the prophylactic point of view, is not practicable in the present economic conditions of Portugal, putting aside all other arguments against it. There are neither the financial means nor the sanatoriums to provide for the existence of the many thousands of persons such a measure would throw out of work. What is more practicable, and this is done, is the infliction of fines on all hotel or lodging-house keepers and others who let an apartment or a room which has been previously occupied by a tuberculous patient without its having been duly disinfected. No such guarantee exists in England and on taking apartments at the seaside it might so happen that they had just been vacated by someone even in an advanced stage of tuberculosis. In Portugal also the provision of spittoons is much more general than in England and the spittoons are of a better model. They are of enamelled metal on stands, so as to be raised 18 inches or two feet from the ground. The expectoration is thus not so likely to fall on the floor but is immersed in the disinfecting solution that is within the spittoon. These spittoons are to be found in every sort of building where the public is likely to congregate, including the churches. Though I have visited many countries I do not remember having seen anywhere such ample provision of spittoons as at Lisbon. This is a simple and inexpensive precaution and yet it must be of great practical service in preventing the contamination of the atmosphere by desiccated sputum. The civil governors have the right to enact by-laws by which persons who do not avail themselves of the spittoon but spit on the ground can be prosecuted and fined.

So thoroughly is tuberculosis considered a contagious disease that the hospital for the treatment of this malady is on the same grounds as the hospital for the isolation of infectious or contagious fevers. This is situated in the district of Rego on an open, uninhabited space to the north of Lisbon. The larger portion of the grounds is devoted to the treatment of epidemic diseases. In the centre there is a broad tree-planted avenue with seven one-storey pavilions on each side. These pavilions hold 33 beds. Then behind them there are smaller structures, some with only six beds and others with 15 beds. Thus various diseases can be readily separated from each other. In normal times only a few of the pavilions are occupied, but the beds are in readiness and in a few hours any of the reserve buildings would be prepared to receive patients. Altogether there are for both sexes 516 beds.

A railing and a garden separate this fever hospital from another cluster of buildings designed for the treatment of tuberculosis. The two services seemed to me very near each other. This proximity may be useful in economising trouble and cost of land and administration, but I am doubtful if it is altogether wise to keep tuberculous patients in the neighbourhood of infectious fevers, and notably of small-pox. There are 212 beds for cases of tuberculosis in a simple building three storeys high. Very ample space is given. No curtains are allowed; everything is beautifully white, clean, enamelled, and easy to wash. There is a broad expanse of country to look out upon from the windows. Six-inch apertures near the ceiling and near the floor assure a current of air when the windows are closed. At the end of the dormitories a splendid sitting room and dining room is provided, three of the walls being entirely of glass and giving on to broad verandahs, and here the patients, though sheltered, enjoy the open air. A large portion of the glass framework is on hinges and can be opened so that the air has free access to the dining room. Nevertheless, and for semi-outdoor treatment, I much prefer the pavilion which I have already described when speaking of the Estaphania Hospital.[1] As this structure is of but one floor the entire length of the apex of the roof is open, a smaller roof being placed over the aperture to prevent the rain entering but leaving space for the passage of air. The flooring stands some distance off the ground which is covered with concrete and kept dry. The boards do not touch each other so that air enters between each board and for the whole length of the ward. Then there are all round windows and doors giving on to a terrace and verandah. Thus air gains access to the patients from all directions, yet they are sheltered from rain and the sun. At the hospital for tuberculosis the dirty linen is not carried out of the wards and down the stairs but is dropped into a shaft, where it falls into a metallic receptacle placed at the bottom. This receptacle stands on wheels, so that it can be readily conveyed to the laundry or the disinfecting station, which are not far away. The dust, the sweepings, and the refuse are also placed in closed metallic receptacles and wheeled away to be destroyed in the furnace or used as manure. At the disinfection station there is a bath for the employees. Policemen, cabmen, ambulance men, and others who assist to bring patients are all bathed, and their clothes are disinfected before they are allowed to return to town. The homes of tuberculous patients are also disinfected by the authorities and this is done gratuitously for the poor.

By far the largest hospital at Lisbon is next door to the new medical schools which were inaugurated by the Fifteenth International Congress of Medicine. A large portion of this building was originally a convent, and outside the main entrance there still remain 12 fine statues of the Apostles. Inside a majestic staircase and hall are ornamented with Portuguese delf tiles which represent hunting scenes, while the roof is painted with beautiful fruit and flowers. These topics can scarcely be considered suitable either for a convent or for a hospital, yet they have been recently restored and convey an impression of grandeur which, in any case, is a pleasant variation of what is usually seen at hospitals. From

nature of the gathering ground it is largely influenced by the method and thoroughness of filtration. While the nature of the gathering ground cannot be altered, Dr. Jenkins thinks that much might be done to lessen the discolouration by rejecting the first water after a drought by means of the by-wash. The principal reservoir has a capacity for 200,000,000 gallons and during its formation the peat naturally present in the soil of the upper portion was not, it appears, thoroughly removed. Dr. Jenkins is evidently of opinion that if the mechanical filtration were supplemented by filtration through sand there would be much less cause for complaint. It is unsatisfactory to find that on the occasion of one of his visits to the waterworks the water was being supplied without undergoing any form of filtration at all. The district council ought to have no difficulty in requiring a proper supply to be given, for in the Act of Parliament under which the company secured the right of supply it is provided that the water shall not only be pure and wholesome but that it shall be "efficiently filtered." But since the beginning of the present year a portion of the supply has been affected in another direction. It has been found to have a distinctly plumbo-solvent action. A year ago there was not known to exist in the Rhondda valleys a single case of lead poisoning attributable to water-borne lead, while at the present time there are under observation by the medical men in the district at least a dozen cases, some of them exhibiting severe symptoms of paralysis. The localities principally affected are those in the lower part of the great valley. The quantity of lead present in the water distributed there and which had been in contact for several hours with the lead service pipes varied from 1 to 5·2 parts per million. Early in June the inhabitants were warned by placards to abstain from drinking water after it had stood in the lead service pipe, especially that first drawn in the morning, and were advised to draw off at least a gallon before using a supply for cooking or drinking. This latter suggestion has called forth a protest from the water company on the ground that if it is followed there will be a waste of water.

---

Schools and Infectious Diseases in Gloucestershire.

In the annual report of the medical officer of health of Gloucestershire Dr. J. Middleton Martin states that the work of district councils in dealing with infectious diseases is increased by the aggregation of children in schools. During epidemics, more especially of diphtheria, the usual public health staff is inadequate to meet the outbreaks if they are to be controlled as it is now known they can be controlled. Emphasis is given to this opinion by an account of two distinct outbreaks of diphtheria which occurred in different parts of the county during 1905, and which were dealt with on different lines. In one outbreak, which occurred in the Thornbury rural district, material from the throats and noses of all the school children—372 in number—was examined bacteriologically, when it was found that in 75 per cent. there was present either the Klebs-Löffler bacillus or a highly suspicious organism closely related to it. In 21 per cent. of the children the bacillus was found in the nose only. The schools were kept open, and during three weeks the throats and noses of all the children were sprayed by the local medical practitioner and the disease was stamped out. The second outbreak was in the Lydney rural district and lasted from the end of 1904 to the beginning of the present year. It was not found possible to carry out the very complete measures which were adopted in the case of the Thornbury outbreak, and the closing of the schools is said to have been quite ineffectual in checking the progress of the disease.

An Unusual Case under the Workmen's Compensation Act.

At the Plymouth county court on August 15th, before his honour Judge Lush-Wilson, K.C., the relatives of a labourer claimed £156 from the proprietor of a quarry at Saltash. Evidence showed that the deceased, who had worked for the defendant for a month, injured his thumb; he remained at home for a week, then resumed his employment, and next day tetanus set in which proved fatal. Medical attention was not procured until tetanus supervened. It was stated that a few days after the accident the deceased had a scuffle with another man when both fell down. His honour, in awarding the relatives £40 compensation, said he held there was sufficient proof that death was the result of the accident.

Falmouth Oysters and Contamination.

Some three or four years ago certain oyster beds at Falmouth were condemned as being contaminated with sewage, and the seizure recently of a large quantity of oysters by the metropolitan authorities has again drawn local attention to the matter. It is only oysters which come from certain areas of the Falmouth district which are contaminated; Helford, St. Mawes, and St. Just areas are perfectly pure, and oysters are sent from there to many parts of the country where they are received without question. The only method of relieving the present state of affairs is to compel all the local authorities whose sewage pollutes the waters and the beds to remove the source of contamination. This is a large undertaking but it will have to be considered.

August 21st.

SCOTLAND.

(From our own Correspondents.)

The Condition of Flock Beds.

During the last two months Dr. R. M. Buchanan, the bacteriologist to the corporation of Glasgow, has examined nine samples of bed-flock which he received from the sanitary inspector. Experimental tests were also undertaken with new flock beds direct from the warehouse and with flock beds which had been in use for some time. For the latter purpose six houses were visited in the east end of the city. The general result of the investigations has served once more to demonstrate that flock, especially of the cheaper qualities, has a bacterial flora indicating an extreme degree of filthiness.

The Natives of St. Kilda and Vaccination.

The inhabitants of the island of St. Kilda, who for so many months of the year are isolated from the rest of the world, evidently do not appreciate the advantages of vaccination. Dr. Johnston of the Local Government Board visited the island this month with a view to vaccinating the natives and found that the operation was not looked upon with favour. About 60 per cent of the community, however, were successfully vaccinated. Some younger citizens tried to get out of the ordeal by saying that such an operation would disable them for the Fulmac catching season which was near at hand. The able-bodied of those vaccinated are discussing the likelihood of being compensated for loss of time incurred through their compliance. The reason why so many of the inhabitants have not previously been vaccinated is that there is no resident medical man on the island. The last steamer to call at the island for this season leaves at the end of this month, and from that date until the spring of next year there will be no communication between the island and the mainland.

Nairn's New Hospital.

The new Town and County Hospital buildings at Nairn were opened last week by Earl Cawdor. These buildings and site, costing in all £5500, are the munificent gifts of Mr. Alexander Mann of Guayaquil, South America, who is a native of Nairn. The history of the hospital is that as far back as 1842 a scheme was set on foot for providing hospital accommodation for the town and county of Nairn, and in 1846 the hospital was built at a cost of £900. A vast amount of good has been done by this hospital during the past years, but it has not now sufficient accommodation to meet the requirements of the district. In making his gift Mr. Mann has stipulated that his name shall be inscribed nowhere inside the building. At the close of the opening ceremony a message was sent to Mr. Mann by those present expressing their gratitude for his generosity and undertaking that the hospital would be efficiently maintained. Immediately afterwards a three days' bazaar was opened in the public hall in aid of the furnishing and equipment of the new buildings. At the bazaar the total proceeds for the three days amounted to £1450.

The New Laboratories at the University of Glasgow.

The new laboratories in connexion with the chairs of physiology, materia medica, and forensic medicine and public health, which are being erected at a cost of £60,000, are now approaching completion, and it is expected that they will be opened in the spring of next year by the Prince of Wales. The internal arrangement of the building for physiology has been a little delayed pending the appointment of a

Since the last-named date no fresh case of the disease has been reported from Jeddah and it is hoped that the epidemic is at an end. There have been in all 72 cases and the same number of deaths. In addition, one fatal case of the disease occurred at Oandirah, near Jeddah, and two fatal cases at Mecca. Both the Mecca cases were imported from Jeddah. The first was observed on June 7th in the person of a butcher's assistant who arrived at Mecca that day, was removed to hospital at once, and died the following day. The second was observed on July 10th; the patient had arrived from Jeddah that day and died in hospital the following day. No further case has been reported from Mecca. Should no others occur there the Holy City of the Moslems will have escaped as lightly this time as it did in 1897, 1898, and 1899, when it will be recalled plague made its appearance in Jeddah; in the first two of those years Mecca remained entirely free and in 1899 only two cases, both imported from Jeddah, were observed there.

It will be remarked that every case of plague reported in the present outbreak has been fatal. A considerable proportion have only been discovered after death and there has been much difficulty in finding the sick and removing them to hospital and in carrying out the other measures decreed. The population of Jeddah are for the most part uneducated and fanatical and they dread the measures taken by the sanitary authorities more than they do the disease itself. It is almost certain that many cases occurred which were never made known to the authorities. Ordinary feelings of humanity have yielded to this dread of European interference and dead bodies have been found in the streets, thrown out from unknown houses, in order that the latter might not be invaded by the physician and disinfector. In such circumstances there is a natural doubt as to whether the outbreak is really at an end, and the measures imposed against Jeddah are consequently still in force, although many more than the regulation ten days have elapsed since the last reported case.

The pilgrim season of next year has almost begun. The Moslem month of Redjeb, the first of the six months of pilgrimage, begins this year on August 20th. The Board of Health has already decreed a series of measures intended to prevent the infection attacking pilgrims arriving in the Hedjaz from other parts of the world. These measures (which may, however, be modified now that the outbreak appears to be at an end) may be summarised as follows. The Government has been asked to advance some £T.5000 to cover the cost of the measures and to send six medical men to Jeddah. The board has sent three disinfectors and six sanitary guards to that port, together with a supply of drugs, disinfectants, and plague serum. All pilgrims arriving at Jeddah will, after undergoing quarantine at the Abou-Saad lazaret, land at Ras-el-Assouad, a spot some 10 or 12 miles to the south of Jeddah, and will not communicate with the town, the local authorities being requested to provide camels and other means of transport to enable them to set out for Mecca as soon as they land. Goods will, in like manner, be despatched to the interior by way of Ras-el-Assouad. A sanitary post is to be established either at Haddé or Bahré, both of which are about half way between Jeddah and Mecca; pilgrims will undergo a medical visit here and any sick will be detained. On arriving at Mecca they will be subjected to another medical visit and to medical surveillance for five days "à domicile," so far as that may be practicable. This measure should not be so difficult of application as it appears at first sight, since the majority of pilgrims are lodged in registered lodging-houses. There must, however, be a considerable number of them who do not go to such houses and who sleep in the streets and open places, or in any corner where they can lay their heads. This scheme of measures is largely based on a similar scheme adopted in the three years mentioned above, when Jeddah was the scene of an outbreak such as the present one. Unfortunately it involves the entire avoidance of the town of Jeddah by the thousands of pilgrims from abroad, and as the townspeople of Jeddah largely depend for their existence upon what they are able to make out of these pilgrims there will be strong opposition to the measures upon their part. It will be recalled that such opposition led to serious riots in the years mentioned. It may be hoped, therefore, that the apparent subsidence of plague in Jeddah may prove to be real, and to admit of a modification of the measures in question in order to avoid the repetition of such riots. In the meantime efforts are being made to improve the sanitary state of the town, but upon this matter I shall hope to send you at an early date some further information from personal observations made during a stay in that interesting town.

The outbreak of plague in Trebizond was first made known here on August 8th. The first cases were seen by the health officer of that port on the afternoon of that day. He was asked by the authorities to visit some suspicious cases in the town prison, and he found three prisoners sick of the disease and the body of a fourth already dead. The details of the four cases were as follows:—

Case 1, aged 35 years, had arrived from Constantinople 28 days previously; he was said to have fallen ill on August 7th; the symptoms as described were those of an acute attack of plague, with a right inguinal bubo. He became comatose and died at midday on the 8th. The body presented no abnormal signs save the bubo and some large spots of ecchymosis.

Case 2, aged 22 years, in prison for eight months. He fell ill on the 7th, with the symptoms of plague and several enlarged glands in the left groin.

Case 3, aged 34 years, fell ill on the 6th, with similar symptoms; bubo in the groin of the size of a hen's egg.

Case 4, aged 28 years, also fell ill on the 6th, with almost identical symptoms; there were enlarged glands in the left groin and axilla.

Other cases have since occurred in the same prison and up to August 14th there had been in all eight cases with four deaths. The outbreak has so far been confined to the prison. This is apparently a large building, containing some 700 prisoners, and it is stated that in the room in which the first cases occurred, and which measures only some 60 square metres, no less than 72 prisoners were lodged. It is not easy or pleasant to imagine what the sanitary condition of such an institution must be. The Board of Health has urged the authorities to evacuate the building completely and to disinfect it thoroughly, no half measures being admissible in presence of such a "foyer" of disease. The origin of the infection is entirely unknown and it is remarkable that the disease has made its appearance in a prison. It is, however, stated that a mortality among rats had been observed in the prison for some ten days before any of the prisoners were attacked. No bacteriological inquiry has yet been made, but a bacteriologist has now been sent from Constantinople to make such inquiry. From the details already furnished there seems, however, to be little doubt that the outbreak is one of bubonic plague. So far as is known the nearest places to Trebizond where plague is now prevalent are the Persian province of Seistan on the one hand, and on the other the ports of Alexandria and Port Said.

In addition to the various measures (isolation, disinfection, &c.) that the Government authorities have been urged to take in the prison and town of Trebizond, the Board of Health has imposed a medical visit upon persons leaving the town by sea, a second medical visit, with disinfection and application of the rat-destruction regulations (the whole not to delay the ship more than 48 hours) in the lazaret of Sinope, and, for those passing the Bosphorus, a third medical visit at Kavak, at the northern end of the Bosphorus.

Constantinople, August 16th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Rhondda Water-supply.

THE unsatisfactory nature of the water-supply in one portion of the Rhondda valleys has been frequently commented on in THE LANCET. Until quite recently the only cause for complaint arose from the peaty discolouration of the water, and although attempts have been made by the water company to remove this condition they do not appear to have been successful. Five or six years ago the inside of the mains was thoroughly scraped and a large amount of deposit was removed. About the same time a set of mechanical filters was installed. These remedial measures only partially succeeded, and at the last meeting of the urban district council the medical officer of health (Dr. J. D. Jenkins) presented a report on the subject which disclosed a serious situation and such as the council can hardly ignore. The amount of discolouration in the water varies considerably, and although due primarily to the

nature of the gathering ground it is largely influenced by the method and thoroughness of filtration. While the nature of the gathering ground cannot be altered, Dr. Jenkins thinks that much might be done to lessen the discolouration by rejecting the first water after a drought by means of the by-wash. The principal reservoir has a capacity for 200,000,000 gallons and during its formation the peat naturally present in the soil of the upper portion was not, it appears, thoroughly removed. Dr. Jenkins is evidently of opinion that if the mechanical filtration were supplemented by filtration through sand there would be much less cause for complaint. It is unsatisfactory to find that on the occasion of one of his visits to the waterworks the water was being supplied without undergoing any form of filtration at all. The district council ought to have no difficulty in requiring a proper supply to be given, for in the Act of Parliament under which the company secured the right of supply it is provided that the water shall not only be pure and wholesome but that it shall be "efficiently filtered." But since the beginning of the present year a portion of the supply has been affected in another direction. It has been found to have a distinctly plumbo-solvent action. A year ago there was not known to exist in the Rhondda valleys a single case of lead poisoning attributable to water-borne lead, while at the present time there are under observation by the medical men in the district at least a dozen cases, some of them exhibiting severe symptoms of paralysis. The localities principally affected are those in the lower part of the great valley. The quantity of lead present in the water distributed there and which had been in contact for several hours with the lead service pipes varied from 1 to 5·2 parts per million. Early in June the inhabitants were warned by placards to abstain from drinking water after it had stood in the lead service pipe, especially that first drawn in the morning, and were advised to draw off at least a gallon before using a supply for cooking or drinking. This latter suggestion has called forth a protest from the water company on the ground that if it is followed there will be a waste of water.

Schools and Infectious Diseases in Gloucestershire.

In the annual report of the medical officer of health of Gloucestershire Dr. J. Middleton Martin states that the work of district councils in dealing with infectious diseases is increased by the aggregation of children in schools. During epidemics, more especially of diphtheria, the usual public health staff is inadequate to meet the outbreaks if they are to be controlled as it is now known they can be controlled. Emphasis is given to this opinion by an account of two distinct outbreaks of diphtheria which occurred in different parts of the county during 1905, and which were dealt with on different lines. In one outbreak, which occurred in the Thornbury rural district, material from the throats and noses of all the school children—372 in number—was examined bacteriologically, when it was found that in 75 per cent. there was present either the Klebs-Löffler bacillus or a highly suspicious organism closely related to it. In 21 per cent. of the children the bacillus was found in the nose only. The schools were kept open, and during three weeks the throats and noses of all the children were sprayed by the local medical practitioner and the disease was stamped out. The second outbreak was in the Lydney rural district and lasted from the end of 1904 to the beginning of the present year. It was not found possible to carry out the very complete measures which were adopted in the case of the Thornbury outbreak, and the closing of the schools is said to have been quite ineffectual in checking the progress of the disease.

An Unusual Case under the Workmen's Compensation Act.

At the Plymouth county court on August 15th, before his honour Judge Lush-Wilson, K.C., the relatives of a labourer claimed £156 from the proprietor of a quarry at Saltash. Evidence showed that the deceased, who had worked for the defendant for a month, injured his thumb; he remained at home for a week, then resumed his employment, and next day tetanus set in which proved fatal. Medical attention was not procured until tetanus supervened. It was stated that a few days after the accident the deceased had a scuffle with another man when both fell down. His honour, in awarding the relatives £40 compensation, said he held there was sufficient proof that death was the result of the accident.

Falmouth Oysters and Contamination.

Some three or four years ago certain oyster beds at Falmouth were condemned as being contaminated with sewage, and the seizure recently of a large quantity of oysters by the metropolitan authorities has again drawn local attention to the matter. It is only oysters which come from certain areas of the Falmouth district which are contaminated; Helford, St. Mawes, and St. Just areas are perfectly pure, and oysters are sent from there to many parts of the country where they are received without question. The only method of relieving the present state of affairs is to compel all the local authorities whose sewage pollutes the waters and the beds to remove the source of contamination. This is a large undertaking but it will have to be considered.

August 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Condition of Flock Beds.

DURING the last two months Dr. R. M. Buchanan, the bacteriologist to the corporation of Glasgow, has examined nine samples of bed-flock which he received from the sanitary inspector. Experimental tests were also undertaken with new flock beds direct from the warehouse and with flock beds which had been in use for some time. For the latter purpose six houses were visited in the east end of the city. The general result of the investigations has served once more to demonstrate that flock, especially of the cheaper qualities, has a bacterial flora indicating an extreme degree of filthiness.

The Natives of St. Kilda and Vaccination.

The inhabitants of the island of St. Kilda, who for so many months of the year are isolated from the rest of the world, evidently do not appreciate the advantages of vaccination. Dr. Johnston of the Local Government Board visited the island this month with a view to vaccinating the natives and found that the operation was not looked upon with favour. About 60 per cent of the community, however, were successfully vaccinated. Some younger citizens tried to get out of the ordeal by saying that such an operation would disable them for the Fulmac catching season which was near at hand. The able-bodied of those vaccinated are discussing the likelihood of being compensated for loss of time incurred through their compliance. The reason why so many of the inhabitants have not previously been vaccinated is that there is no resident medical man on the island. The last steamer to call at the island for this season leaves at the end of this month, and from that date until the spring of next year there will be no communication between the island and the mainland.

Nairn's New Hospital.

The new Town and County Hospital buildings at Nairn were opened last week by Earl Cawdor. These buildings and site, costing in all £5500, are the munificent gifts of Mr. Alexander Mann of Guayaquil, South America, who is a native of Nairn. The history of the hospital is that as far back as 1842 a scheme was set on foot for providing hospital accommodation for the town and county of Nairn, and in 1846 the hospital was built at a cost of £900. A vast amount of good has been done by this hospital during the past years, but it has not now sufficient accommodation to meet the requirements of the district. In making his gift Mr. Mann has stipulated that his name shall be inscribed nowhere inside the building. At the close of the opening ceremony a message was sent to Mr. Mann by those present expressing their gratitude for his generosity and undertaking that the hospital would be efficiently maintained. Immediately afterwards a three days' bazaar was opened in the public hall in aid of the furnishing and equipment of the new buildings. At the bazaar the total proceeds for the three days amounted to £1450.

The New Laboratories at the University of Glasgow.

The new laboratories in connexion with the chairs of physiology, materia medica, and forensic medicine and public health, which are being erected at a cost of £60,000, are now approaching completion, and it is expected that they will be opened in the spring of next year by the Prince of Wales. The internal arrangement of the building for physiology has been a little delayed pending the appointment of a

Since the last-named date no fresh case of the disease has been reported from Jeddah and it is hoped that the epidemic is at an end. There have been in all 72 cases and the same number of deaths. In addition, one fatal case of the disease occurred at Candirah, near Jeddah, and two fatal cases at Mecca. Both the Mecca cases were imported from Jeddah. The first was observed on June 7th in the person of a butcher's assistant who arrived at Mecca that day, was removed to hospital at once, and died the following day. The second was observed on July 10th; the patient had arrived from Jeddah that day and died in hospital the following day. No further case has been reported from Mecca. Should no others occur there the Holy City of the Moslems will have escaped as lightly this time as it did in 1897, 1898, and 1899, when it will be recalled plague made its appearance in Jeddah; in the first two of those years Mecca remained entirely free and in 1899 only two cases, both imported from Jeddah, were observed there.

It will be remarked that every case of plague reported in the present outbreak has been fatal. A considerable proportion have only been discovered after death and there has been much difficulty in finding the sick and removing them to hospital and in carrying out the other measures decreed. The population of Jeddah are for the most part uneducated and fanatical and they dread the measures taken by the sanitary authorities more than they do the disease itself. It is almost certain that many cases occurred which were never made known to the authorities. Ordinary feelings of humanity have yielded to this dread of European interference and dead bodies have been found in the streets, thrown out from unknown houses, in order that the latter might not be invaded by the physician and disinfector. In such circumstances there is a natural doubt as to whether the outbreak is really at an end, and the measures imposed against Jeddah are consequently still in force, although many more than the regulation ten days have elapsed since the last reported case.

The pilgrim season of next year has almost begun. The Moslem month of Redjeb, the first of the six months of pilgrimage, begins this year on August 20th. The Board of Health has already decreed a series of measures intended to prevent the infection attacking pilgrims arriving in the Hedjaz from other parts of the world. These measures (which may, however, be modified now that the outbreak appears to be at an end) may be summarised as follows. The Government has been asked to advance some £T.5000 to cover the cost of the measures and to send six medical men to Jeddah. The board has sent three disinfectors and six sanitary guards to that port, together with a supply of drugs, disinfectants, and plague serum. All pilgrims arriving at Jeddah will, after undergoing quarantine at the Abou-Saad lazaret, land at Ras-el-Assouad, a spot some 10 or 12 miles to the south of Jeddah, and will not communicate with the town, the local authorities being requested to provide camels and other means of transport to enable them to set out for Mecca as soon as they land. Goods will, in like manner, be despatched to the interior by way of Ras-el-Assouad. A sanitary post is to be established either at Haddé or Bahré, both of which are about half way between Jeddah and Mecca; pilgrims will undergo a medical visit here and any sick will be detained. On arriving at Mecca they will be subjected to another medical visit and to medical surveillance for five days "à domicile," so far as that may be practicable. This measure should not be so difficult of application as it appears at first sight, since the majority of pilgrims are lodged in registered lodging-houses. There must, however, be a considerable number of them who do not go to such houses and who sleep in the streets and open places, or in any corner where they can lay their heads. This scheme of measures is largely based on a similar scheme adopted in the three years mentioned above, when Jeddah was the scene of an outbreak such as the present one. Unfortunately it involves the entire avoidance of the town of Jeddah by the thousands of pilgrims from abroad, and as the townspeople of Jeddah largely depend for their existence upon what they are able to make out of these pilgrims there will be strong opposition to the measures upon their part. It will be recalled that such opposition led to serious riots in the years mentioned. It may be hoped, therefore, that the apparent subsidence of plague in Jeddah may prove to be real, and to admit of a modification of the measures in question in order to avoid the repetition of such riots. In the meantime efforts are being made to improve the sanitary state of the town, but upon this matter I shall hope to send you at an early date some further information from personal observations made during a stay in that interesting town.

The outbreak of plague in Trebizond was first made known here on August 8th. The first cases were seen by the health officer of that port on the afternoon of that day. He was asked by the authorities to visit some suspicious cases in the town prison, and he found three prisoners sick of the disease and the body of a fourth already dead. The details of the four cases were as follows:—

Case 1, aged 35 years, had arrived from Constantinople 28 days previously; he was said to have fallen ill on August 7th; the symptoms as described were those of an acute attack of plague, with a right inguinal bubo. He became comatose and died at midday on the 8th. The body presented no abnormal signs save the bubo and some large spots of ecchymosis.

Case 2, aged 22 years, in prison for eight months. He fell ill on the 7th, with the symptoms of plague and several enlarged glands in the left groin.

Case 3, aged 34 years, fell ill on the 6th, with similar symptoms; bubo in the groin of the size of a hen's egg.

Case 4, aged 28 years, also fell ill on the 6th, with almost identical symptoms; there were enlarged glands in the left groin and axilla.

Other cases have since occurred in the same prison and up to August 14th there had been in all eight cases with four deaths. The outbreak has so far been confined to the prison. This is apparently a large building, containing some 700 prisoners, and it is stated that in the room in which the first cases occurred, and which measures only some 60 square metres, no less than 72 prisoners were lodged. It is not easy or pleasant to imagine what the sanitary condition of such an institution must be. The Board of Health has urged the authorities to evacuate the building completely and to disinfect it thoroughly, no half measures being admissible in presence of such a "foyer" of disease. The origin of the infection is entirely unknown and it is remarkable that the disease has made its appearance in a prison. It is, however, stated that a mortality among rats had been observed in the prison for some ten days before any of the prisoners were attacked. No bacteriological inquiry has yet been made, but a bacteriologist has now been sent from Constantinople to make such inquiry. From the details already furnished there seems, however, to be little doubt that the outbreak is one of bubonic plague. So far as is known the nearest places to Trebizond where plague is now prevalent are the Persian province of Seistan on the one hand, and on the other the ports of Alexandria and Port Said.

In addition to the various measures (isolation, disinfection, &c.) that the Government authorities have been urged to take in the prison and town of Trebizond, the Board of Health has imposed a medical visit upon persons leaving the town by sea, a second medical visit, with disinfection and application of the rat-destruction regulations (the whole not to delay the ship more than 48 hours) in the lazaret of Sinope, and, for those passing the Bosphorus, a third medical visit at Kavak, at the northern end of the Bosphorus.

The New Laboratories at the University of Glasgow.

The new laboratories in connexion with the chairs of physiology, materia medica, and forensic medicine and public health, which are being erected at a cost of £60,000, are now approaching completion, and it is expected that they will be opened in the spring of next year by the Prince of Wales. The internal arrangement of the building for physiology has been a little delayed pending the appointment of a

new professor to the chair, but now that Professor D. Noel Paton has been appointed his views on the matter will be able to be ascertained and there is not likely to be any further delay. The opening of the new laboratory for natural philosophy has rendered it possible to hold for the first time this summer a practical class in physics for medical students. This class was not made compulsory, but it was found that almost every student who had entered for the lectures also took out the practical class.

August 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Typhoid Fever in Belfast.

AT a meeting of the public health committee of Belfast held on August 18th it was reported, as many of your readers may know, that cases of typhoid fever had occurred in the southern part of the city, and instructions were given for the energetic prosecution of investigations to trace the origin of the disease. The outbreak has occurred in Adelaide Park, Cadogan Park, and the neighbouring residential district for the well-to-do classes. It is hoped that the cause of this outbreak, whether milk, water, or defective drains, will be found out promptly, for at present, it will be remembered, Belfast, being without a medical superintendent officer of health, is not in a favourable position to withstand an epidemic.

Fire at the Throne Hospital, Belfast.

On Saturday last, August 18th, a fire, which is believed to have had its origin in a faulty chimney, broke out in the children's wing of the Throne Hospital, the convalescent institution connected with the Royal Victoria Hospital, which is situated about four miles from Belfast. The city fire brigade was at once summoned, while all the children were safely removed. Fortunately, after some hard work by the brigade the risk of the fire destroying the whole building was overcome and the damage was limited to the children's wing. The roof of this was completely destroyed, while the fabric was very much injured by fire, smoke, and water. Thanks to the efforts of the salvage corps the beds, bedding, and other articles of furniture were saved. The little patients, who were transferred to another portion of the building, have proved to be none the worse for their adventure. The loss is covered to a certain extent by insurance.

Tuberculosis in Pork.

A meeting of the city council of Belfast in committee was held on Monday last, August 20th, to consider the question of dealing with tuberculosis in pork. On July 28th the market committee passed, after long consideration, the following proposition:—

> That in all well-nourished carcasses of pigs, where the tuberculosis is strictly confined to the glands of the neck, the head only, or such portion as is affected by the disease, shall be destroyed, the remainder of the carcass being handed back to the owner, and that in the case of all carcasses showing unmistakeable evidence of the disease having become generalised—i.e., two or more organs affected—the whole of every such carcass shall be destroyed.

When the matter came before the city council at the beginning of August it was decided to refer the subject to the market committee, which, after careful consideration of all the facts, reaffirmed its resolution. On August 20th this was reported to the council in committee, called specially to receive the market committee's report, and after considerable discussion the market committee's resolution was adopted by a majority of two. An amendment to adjourn the matter for a month for the market committee to obtain expert evidence on the whole question in the interval was lost.

The late Mr. G. L. B. Stoney, L.R.C.P., L.R.C.S. Irel.

Mr. Stoney died at his residence, Lucan, co. Dublin, on August 8th. For the last 30 years he was well known and highly esteemed in the district, while he made many friends among the visitors who stay at the Hydropathic Hotel and ink the sulphur spa water. He was the author of the port on the Lucan Spas, and Lucan as a Health Resort," a great deal to make the place popular. He was ficer of the Lucan Dispensary district.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Alcoholism in France.

IF we may judge of the progress of alcoholism in France by the increase in the number of public-houses the result gives very little encouragement to those who are striving against the alcohol plague. As a matter of fact, the number of public-houses continues to increase and alcoholism increases *pari passu*. In 1904 there were 468,434 places for the sale of alcohol open. In 1905 the number had increased to 473,593.

A Curative Product Derived from Tuberculinine.

At a meeting of the Academy of Sciences held on August 6th M. Baudran read a paper wherein he said that being convinced that the bacillus tuberculosis contains a toxic body of alkaloidal nature, to which he has given the name tuberculinine, he had been enabled to isolate this body in a crystalline state and from it to obtain a substance possessing curative properties. He treated tuberculinine with permanganate of calcium and then injected it into healthy guinea-pigs in doses of 0·0008 of a gramme. The guinea-pigs died within a period of from eight to 15 days after the injection. M. Baudran was thus enabled to obtain an antitoxin which injected in doses of one cubic centimetre as a preventive 12 hours before an injection of tuberculinine in healthy guinea-pigs enabled them to receive on the following day a fatal dose of tuberculinine without dying. With regard to the curative properties of this substance encouraging experiments had been made upon both guinea-pigs and bovine animals. Moreover, M. Baudran had observed upon himself that subcutaneous injections of the antitoxin were painless and did not cause any rise of temperature or any other trouble even when the injections were continued for several weeks.

The Paris Hospitals.

For the last year many works have been undertaken at the Paris hospitals. In two of the hospitals these works have come to an end and the new buildings are in working order. At the Lariboisière Hospital great enlargements have been carried out. A new block has been built, altogether reserved for medical and surgical consultation. New operation theatres have been built, all the kitchens have been reconstructed, and a model laundry has also been put up. In the new consulting rooms the angles are all rounded off; the floor is tiled and the walls are varnished. Besides rooms for ordinary medical and surgical work special departments have been erected for electro-therapy, oto-rhino-laryngology, and ophthalmology. In the laundry the dirty linen is disinfected, washed, dried, and done up mechanically. At the St. Antoine Hospital the work carried out has cost about 2,000,000 francs and the hospital will in future be able to provide for nearly 1000 patients in lieu of 800 as formerly. Large consulting rooms have been built upon a new style. The patients undress in a separate room before going into the physician's room and they are examined separately. A magnificent building has been put up for the staff. Finally, the Andral Hospital having been done away with has been replaced by Bastion 27, which has been arranged as an ordinary hospital.

The Expenses of Justice.

The Director of Criminal Prosecutions desiring to diminish the expenses of legal proceedings has just sent out a circular to *procureurs généraux* pointing out various petty economics which they could carry out. Naturally, most of these small economies are directed against medical men. As it is, the fees paid to medical men for the loss of their time are laughable, so much so that in numerous small towns there is great difficulty in finding any medical man who will take up the work of a medical expert; and now, apparently, even the small sums paid to such experts are going to be diminished. In cases of misdemeanour, for instance, the fee for a medical report will only be 5 francs. Experts in mental diseases cannot be summoned unless there is some presumptive evidence of intellectual trouble or if they are demanded by counsel, who must justify the necessity of calling in such evidence. Laboratory expenses for chemical analysis are also to be reduced as much as possible. The circular puts forward a desire that in workmen's compensation cases a maximum sum should be laid down for a fee, in h cases as have no exceptional character. In trials ried out *in formâ pauperis* the circular requests that all dical men in place of coming themselves to court to give ir report should send this by post to the president of the urt. This measure is not a very happily conceived one, often it happens that objection is taken to the evidence the medical men and in this case there will be no oppor- ity of hearing their answers to such objections.

(FROM OUR OWN CORRESPONDENT.)

The Serum Treatment of Puerperal Fever.

Professor Martin of Greifswald, writing to the *Berliner 'inische Wochenschrift*, says that of the two modern prin- ples of treating puerperal fever—namely, by surgical ethods and by injections of antitoxin—the former is avail- le only in clinics and hospitals, whilst the latter may be rried out by any practitioner. Opinions, however, differ eatly as to the efficacy of serum treatment owing to the ant of a satisfactory system of comparing cases. Professor artin has endeavoured to arrive at a definite result by bulating the incidence of pyrexia in puerperal patients cording as they were treated with or without serum. e said that since June 1st, 1905, all cases of ierperal fever under his care have been treated by ntitoxin and he compares the cases which occurred from at date till June 1st, 1906, with the corresponding numbers the previous year when serum treatment was not yet in se. In the administration of the antitoxin 20 cubic centi- etres were injected when the rectal temperature was igher than 38·5° C.; if the temperature was over 38° C. n the following day a second injection and perhaps even a hird injection were given. When the temperature did not all another series of injections was begun on the sixth day. he statistical tables compiled by Professor Martin show that emperatures from 38·5° to 38·9° were attained in 25·6 per ent. of the cases treated without serum and in 28 per cent. f those treated with serum; temperatures from 39° to 39·4° ere attained in 23 per cent. of those treated without serum nd in 32 per cent. of those treated with serum; temperatures rom 39·5° to 39 9° were attained in 20·5 per cent. of those reated without serum and in 24 per cent. of those treated with erum; temperatures from 40° to 40·4° were attained in 23·5 er cent. of those treated without serum and in 8 per cent. of hose treated with serum; and temperatures from 40·5° to 1° were attained in 7·6 per cent. of those treated without erum and 8 per cent. of those treated with serum. Tem- eratures over 40°, therefore, occurred in 31 per cent. of the ases treated without serum but in only 16 per cent. of those reated with it; in the latter the pyrexia was also of shorter uration. Professor Martin therefore recommends that erum treatment should be employed in every case.

The Comparative Frequency of Appendicitis in Men and in Women.

The above question is discussed by Dr. Karrenstein of Altona in the *Deutsche Medizinische Wochenschrift*. In the surgical text-books appendicitis is said to be much more frequent in the male than in the female sex, the proportion varying according to the different statistics from 74 *to* 53 per cent. for males. Dr. Karrenstein, however, maintains that false conclusions have been drawn from the facts. As the statistics are based on hospital cases and as men are admitted to hospitals in much greater numbers than women it is obvious that more men must be treated for appendicitis than women. It was not the absolute number but the frequency of appendicitis in each 1000 men and 1000 women that should be compared. When this was done it was found that in Berlin the numbers of men and women suffering from appendicitis were nearly equal and that in 1899 even more women than men were received, the proportions being 2·99 per 1000 men and 4·20 per 1000 women. In Hamburg a considerable and permanent preponderance of appendicitis in the female sex was found to exist.

The University of Greifswald.

The University of Greifswald in Pomerania lately celebrated its 450th anniversary with great display. Prince August Wilhelm, representing the Emperor, the Minister of Education, and many representatives of the authorities attended the proceedings, which began with Divine service in the cathedral. At a formal meeting of the four faculties, presided over by the rector, Professor Bonet, and in the presence of many official personages and visitors, honorary degrees were conferred on several men of science. The recipients of the honorary degree of M.D. included Professor William Keen of Philadelphia, Professor Roux of the Pasteur Institute at Paris, and Professor Snellen of Utrecht. Considerable sums have been placed at the disposal of the University by some wealthy families of Pomerania for the purpose of providing the university clinics with means for scientific research and for the reception of indigent patients. A special number, consisting exclusively of articles contributed by members of the Greifswald Medical Faculty, has been issued by the *Deutsche Medizinische Wochenschrift*.

Practical Joking by Students.

A paragraph was lately inserted in some daily newspapers to the effect that the medical students of the University of Göttingen had passed a resolution condemning vivisection. It was said in the resolution that vivisection was censurable from the ethical and moral point of view, that it demoralised the teachers as well as the students, and that the students assembled in meeting declined to attend the lectures on physiology and pharmacology as long as experiments on animals were performed. This report caused a great sensation and received the hearty approval of the adherents of "natural" medicine, antivivisectionists, and so on, but their joy was short-lived, for it soon became known that a party of medical students, exhilarated by good German beer, had constituted themselves an antivivisectionists' committee, and that the report of the proceedings at the alleged meeting was the product of their imagination.

August 20th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Recent Illness of the Sultan.

ALL sorts of alarming rumours concerning the recent illness of the Sultan have been circulating in the Ottoman metropolis and doubtless have found their counterpart elsewhere. Last Friday, when Abdul Hamid did not appear to perform the traditional religious ceremony of the so-called Selamlik, it was said that he was already dead, some affirming their knowledge that he was poisoned, having fallen a victim to a palace revolution. The cause of these extraordinary false rumours is the great secrecy which surrounds all things concerning Yildiz-Kiosk, and especially the person of the Sultan. The fact that the Padishah did not attend the Friday Selamlik ceremony was certainly an unusual occurrence, it being the first time during the long reign of Abdul Hamid that this religious military pageant was dispensed with, and no explanation for the departure was too violent for the imagination. The facts concerning the Sultan's illness are as follows and I believe that I have gathered them from trustworthy sources. Abdul Hamid suffers from a chronic enlargement of the prostate gland with all the consequent train of symptoms associated with this malady. As he is over 60 years of age it is not surprising that sometimes these symptoms become more acute. The first manifestations of the condition began to trouble the Sultan about ten years ago, when a German surgeon who was called in recommended operative treatment. The Sultan, however, declined to submit to operation and it is very doubtful if he would be of a different opinion now if Professor Bergman comes to Constantinople, as is stated to be probable. In the meantime the Sultan is undoubtedly better and the chief chamberlain has made a formal announcement that he has *completely recovered* (the italics are mine).

The Civil Medical School at Damascus.

This school was founded three years ago and is doing good work. It contains at present 102 students of whom more than half are studying the practice of medicine. The remainder devote their time particularly to chemistry. The last summer examinations have been brought to a close some days ago. It is intended to enlarge the buildings of the school as the number of students is steadily increasing.

A Laboratory of Chemical Analysis.

It is intended to erect at the prefecture of the capital who had been treating the case ever since. It was submitted that the plaintiff's charges were well within what was regarded as the reasonable scale. Judging from the number of medical witnesses called in the case it would seem that although the defence relied upon the alleged agreement between Dr. Borghetti and the patient's mother a suggestion of improper treatment was likely to be made. The magistrate, in giving his decision in favour of the plaintiff, stated that the operations had been skilfully performed and that the fees charged were moderate.

The New Zealand Meat Trade.

The recent disclosures with regard to the conditions under which the export trade of meat is conducted in America have, it appears, drawn attention to the methods of inspection and surveillance which are exercised over such matters in this colony and the Commonwealth of Australia. This, I am certain, can only tend to the benefit of New Zealand. There is no country in the world where greater care and more scientific skill are employed in the inspection of meat and butter than obtain in this colony. Every carcass is examined by a properly qualified veterinary surgeon and must bear his stamp before the meat can leave the factory. There is every inducement to be honest and none to act otherwise, as compensation is paid to the owners of all condemned stock. At most of the stock sales an inspector is present, but it is upon the post-mortem examination that the certificate depends. Attached to all the meat-exporting companies' works is a Government veterinarian whose sole duty is to examine each animal as it is killed.

Various Items of News.

The Government of New Zealand has invited the various health officers of the Commonwealth to hold their projected conference on inter-State and inter-Colonial quarantine in Christchurch during the time the exhibition is open.—There has been a very regrettable falling off in the number of children vaccinated during the last year. Of those born during that period only about 10 per cent. have been protected. Only the presence of a case of small-pox within the colony will serve to bring the people to a proper sense of the danger.—The campaign against tuberculosis proceeds amain. The hospital boards throughout the colony are gradually seeing the necessity of putting up open-air shelters for receiving not only the curable cases but also that greatest of menaces to the commonweal—the indigent incurable. The latest to undertake this good work is the Thames Hospital Board. The district to which this board ministers is mainly devoted to gold-mining and in consequence there are a great number of men suffering from fibroid tuberculosis and other lung troubles.—A very exhaustive Food and Drugs Bill is to form one of the measures to be dealt with by Parliament next session.

Wellington, July 18th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Karl Kisskalt has been recognised as *privat-docent* of Hygiene.—*Bologna:* Dr. Carlo Comba has been appointed Extraordinary Professor of Children's Diseases.—*Cracow:* Dr. Valerian Jaworski has been promoted to the chair of Clinical Medicine in succession to the late Dr. Korczynski. Dr. Franz Krzysztalowicz, *privat-docent* of Dermatology and Syphilis, has been granted the rank of Extraordinary Professor.—*Gratz:* The rank of Extraordinary Professor has been granted to Dr. Theodor Pfeiffer, *privat-docent* of Internal Medicine.—*Greifswald*: Dr. Karl Ritter, *privat-docent* of Surgery; Dr. Philipp Jung, *privat-docent* of Midwifery and Gynæcology; and Dr. Hermann Schroeder, *privat-docent* of Odontology, have been granted the title of Professor; and Dr. Ernst Schultze, Extraordinary Professor in the Medical Faculty, has been promoted to Ordinary Professor.—*Heidelberg:* Dr. Sarwey of Tübingen has been appointed to the chair of Midwifery and Gynæcology in succession to Dr. Schatz. Dr. Narath of Utrecht has been appointed Professor of Clinical Surgery in succession to Dr. Czerny, resigned.—*Königsberg:* Dr. Wrede has been recognised as *privat-docent* of Surgery.—*Marburg:* Dr. H. Vogt has been recognised as *privat-docent* of Internal Medicine.—*Munich:* Dr. Richard Trommsdorff has been recognised as *privat docent* of Hygiene.—*Naples:* Dr. Rocco Caminiti has been recognised as *privat-docent* of External Pathology.—*Odessa:* Dr. N. Gamaleia has been recognised as *privat-docent* of Bacteriology.—*Padua:* Dr. Giuseppe Favaro has been recognised as *privat-docent* of Anatomy.—*Pavia:* Dr. Umberto Mantegazza has been appointed Professor of Dermatology and Syphiligraphy.—*Rome:* Dr. Giovanni Loriga has been recognised as *privat-docent* of Hygiene.—*Strasburg:* Dr. Ernst Münch has been granted the title of Professor.—*Tübingen:* Dr. Curschmann has been recognised as *privat-docent* of Internal Medicine; Dr. Bonhoeffer of Breslau has been offered the post of Director of the Clinic of Mental Diseases; and Dr. Conrad Sick has been recognised as *privat-docent* of Internal Medicine.—*Zürich:* Dr. H. Bluntschli has been recognised as *privat-docent* of Pathological Anatomy.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Castiaux, professor of forensic medicine in the University of Lille.—Dr. A. Vincent, formerly professor of hygiene in the University of Geneva, and Vice-President of the International Conference on the Revision of the Geneva Convention.—Dr. A. Kliarevski, formerly professor of medical physics in the University of Kieff.—Dr. A. Peride, professor of anatomy in the University of Jassy.—Dr. W. D. Bullard, assistant professor of surgery in the New York Post-Graduate School.

SOCIETY OF APOTHECARIES OF LONDON.—At a meeting of the Court of Assistants held at the Society's Hall, Blackfriars, on August 14th, Mr. E. Parker Young, M.R.C.S. Eng., L.S.A., was chosen as Master, and Mr. George Wilks, M.B., M.R.C.S. Eng., L.S.A., and Mr. F. Gordon Brown, M.R.C.S. Eng., L.S.A., surgeon to the City of London police, were elected respectively as Senior and Junior Wardens for the ensuing year. The customary votes of thanks were given to the out-going Master, Surgeon-General J. H. Jeffcoat, and the Wardens. The court unanimously resolved that the Freedom of the Society should be conferred upon Alderman T. B. Crosby.

COOKERY AND FOOD EXHIBITION.—The Seventeenth Universal Cookery and Food Exhibition is to be held at the Royal Horticultural Hall, Vincent-square, Westminster, from Nov. 27th to Dec. 1st. The exhibition is under the immediate patronage of Her Majesty the Queen and the exhibits are divided into 13 sections. Among these sections are those dealing with foods and food products, elementary cookery as taught in schools, household cookery, invalid cookery, navy and army cookery, a section dealing with bread, and a currant cookery competition. In the elementary cookery section there will be a series of children's competitions open to pupils attending cookery classes in elementary schools, and the competition will consist of suitable dishes for artisans and other simple households. Section 13 consists of competitions to be held in the model kitchen. There are to be competitions in grilling, cooking potatoes, making salads, and making omelettes, but we regret to see no competition for the boiling of plain rice. Plain boiled rice is an excellent substitute for other vegetables with ordinary meat but it is exceedingly rare to get it really well cooked, and we hope that the committee will see its way to adding this competition to those already offered.

THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—His Majesty the King of the Belgians has repeatedly expressed his appreciation of the work done by the Liverpool School of Tropical Medicine for the improvement of health in the tropics. He has especially taken a deep interest in the investigations into sleeping sickness which the school carried out in the Congo Free State for over three years, when the late Dr. J. E. Dutton so lamentably lost his life owing to contracting a very dangerous disease in the investigation of its causes. The school has continued without intermission to prosecute its researches into sleeping sickness and other tropical diseases and His Majesty has kindly invited the chairman, Sir Alfred Jones, K.C.M.G., to present to him at a luncheon at the Palace at Brussels the leading workers of the school on Thursday next. The professor of tropical medicine, the chairman of the professional committee, the Walter Myers lecturer, the director of tropical research at the laboratories at Runcorn, the dean of the school, and several others will, it is hoped, be present. In view of the generous financial support that the King has already given to the school this further courteous token of recognition of the work of the school and especially of the young men of science who risk their lives for humanity is much appreciated and the interview will stimulate still further the energies of the school.

NORTH DEVON INFIRMARY, BARNSTAPLE.—The recent appeal made by Lord Fortescue (Lord Lieutenant of Devon) on behalf of the £4000 required for the renovation of the North Devon Infirmary, Barnstaple, has been very satisfactory and it is now assured that the sum required will be raised.

BRISTOL ROYAL INFIRMARY.—The half-yearly meeting of the governors of this institution was held on August 13th under the presidency of Sir George White. The medical report stated that for the six months ended June 30th last the in-patients numbered 1755, against 1733 for the corresponding period of 1905. 19,598 out-patients were treated, compared with 17,315 for the first half year of 1905. The financial statement showed that the income for the half year was £9346 and the expenditure £9334, leaving a favourable balance of £12. Sir George White alluded to the plans which have been made for the erection of a new out-patient department on a suitable site facing the infirmary. The chairman added that £46,099 had been received towards the "£50,000 Fund" which was required for the purpose of improvements in the institution and appealed to the citizens of Bristol to raise the deficiency of £3901 which is still required.

DONATIONS AND BEQUESTS.—By the will of Mr. W. Rae, of Northampton, L.R.C.P. Edin., M.R.C.S. Eng., £5000 are left to Northampton Town and County Institute for Trained Nurses; £2000 to Northampton County Hospital; £500 each to Northampton Royal Victoria Dispensary and Weston Favell Convalescent Home; £250 each to Northampton Institute for the Blind, St. John Ambulance Association, and Good Samaritan Society; and the residue of his estate, probably about £12 000, to the Institute for Trained Nurses. —A donation of £1000 has been received from Lord Howard de Walden for the emergency fund of Charing Cross Hospital. —The executors of the late Mrs. Hannah Finnie have contributed £1000 to the Royal National Hospital for Consumption at Ventnor for the endowment of a bed to be named "The Hannah Finnie Memorial"; and the Royal Dental Hospital of London, Leicester-square, has received £500 from the executors, with the stipulation that the amount be invested and the income therefrom applied for the objects of the hospital.

DOLGELLY ISOLATION HOSPITAL.—The question of erecting an isolation hospital was further considered by the Dolgelly urban and rural district councils on August 17th and 18th. At the former meeting a letter was read from Mrs. Vaughan who had offered three months ago to provide a site for the purpose, stating that she intended her free gift for the benefit of Dolgelly and the immediate districts. After a long discussion the urban council decided by a majority to defer the matter pending a reply from the rural council which had previously agreed to bear a proportion of the cost. At the meeting of the rural council letters were read from almost all the parishes in the area protesting against the expenditure, the general opinion being that the hospital would be of no benefit to them and that the rates were burdensome. The rural council unanimously agreed to rescind the previous resolution to become responsible for part of the cost and resolved that no further steps should be taken in the matter. While all the members of the urban council are in favour of the hospital, the erection of which has been strongly urged upon them by the medical officer (Dr. Hugh Jones), it appears probable that the matter will be dropped now. The scarlet fever epidemic has abated.

THE PRESERVATION OF WOOD FROM WHITE ANTS.—In *Engineering* of August 17th is an interesting note upon a new process for the preservation of wood from white ants. It is well known what damage these insects do to woodwork in the tropics and in many hospital buildings their ravages have been extremely annoying. The process which *Engineering* describes consists of impregnating the timber with a saccharine solution, to which is added a small portion of a metallic salt, and an illustration which is published in the articles to which we refer shows two pieces of ordinary yellow deal, one of which had been treated and the other of which had not been so. These two pieces had been bolted together and placed by the curator of the Government Botanical Gardens at Singapore in a position where there were many white ants. The termites attacked the non-treated piece and very nearly destroyed it altogether, while the treated piece remained entirely unaffected. The process is carried out by the Powell Wood Process Syndicate, Limited, 28, Fleet-street, London, E.C. If we may judge from the illustration given by *Engineering* the process should be of great value where any wooden structure has to be used in a country infested with white ants.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALLKIN, F. W., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health to the Denton *District* Council.

BECKETT, F. H., M.B., B.C. Cantab., has been appointed Certifying Surgeon under the Factory and *Workshop Act for the Ely District* of the county of Cambridge.

EVANS, JOHN, M.B., B.S. Lond., *M.R.C.S., L.R.C.P. Lond.*, has been appointed *Clinical Assistant* to the Hospital for Consumption and Diseases of the Chest, Brompton.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH, ROYAL UNITED HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

BIRMINGHAM ASYLUM, Rubery-hill.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, &c.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Second House Surgeon, unmarried. Salary £60 per annum, with board, residence, and washing.

BUXTON, DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

CAPE OF GOOD HOPE, GREY HOSPITAL, King William's Town.—Resident House Surgeon, unmarried. Salary at rate of £300 per annum, with quarters and one ration.

CARLISLE, CUMBERLAND INFIRMARY.—Resident Medical Officer. Salary at rate of £80 and £100 per annum, with board, lodging, and washing.

CHESTER GENERAL INFIRMARY.—House Physician. Salary £90 per annum, with residence and maintenance.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Senior House Surgeon. Salary £120 per year, with board, apartments, and laundress.

DORCHESTER, COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £140, rising to £180, with board, lodging, &c.

EDINBURGH, SCHOOL OF MEDICINE OF THE ROYAL COLLEGES.—Lecturership in Physiology.

EGYPTIAN GOVERNMENT, MINISTRY OF EDUCATION.—Professor of Midwifery and Gynæcology. Salary £400 a year. Also Medical Tutor and Registrar to Kasr-el-Ainy Hospital. Salary £400 a year.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Three House Physicians and One House Surgeon. Salaries at rate of £60 per annum, with board and residence. Also Resident Pathologist and Registrar. Salary £100, with board and residence.

LIVERPOOL STANLEY HOSPITAL.—Second and Third House Surgeons. Salary £70 and £60 per annum respectively, with board, residence, and washing.

LIVERPOOL, WORKHOUSE AND HOSPITAL, Rice-lane, Walton.—Assistant Resident Medical Officer, unmarried. Salary £125 per annum, with board.

LONDONDERRY AND NORTH-WEST OF IRELAND EYE, EAR, AND THROAT HOSPITAL.—Honorary Surgeon.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—Junior Resident Medical Officer, unmarried. Salary at rate of £80 a year, with board and lodging.

MANCHESTER HOSPITAL FOR CONSUMPTION.—Assistant Medical Officer for Crossley Sanatorium, Delamere Forest. Also Resident Medical Officer for Hospital at Bowdon. Salary in each case £100 per annum, with board, &c.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood.—Resident Medical Officer. Honorarium £50 per annum, including board, lodging, &c.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £70 per annum, with board, residence, and washing.

PETERBOROUGH INFIRMARY AND DISPENSARY.—Physician and Assistant Physician.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Third Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

WARRINGTON UNION WORKHOUSE.—Resident Medical Officer, unmarried. Salary £130 per annum, with apartments, rations, and allowances.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Two House Physicians and Three House Surgeons for six months. Board, lodging, and laundry provided.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Physician for six months. Salary at rate of £75 per annum, with board, lodging, and washing.

YORK COUNTY HOSPITAL.—House Physician. Salary £100 per annum, with board, residence, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Stepney, in the county of London; at Corris, in the county of Merioneth; and at Dawlish, in the county of Devon.

Births, Marriages, and Deaths.

BIRTHS.

JACOB.—On August 14th, at Hindes-road, Harrow, the wife of Archibald H. Jacob, L.R.C.P. & C.S. Irel., of a daughter.

SELIGMANN.—On August 14th, at York-terrace, Regent's Park, the wife of Charles G. Seligmann, M.B., of a daughter.

MARRIAGES.

MCALLUM—COOKE.—On August 18th, at St. Jude's Church, Southsea, Donald C. A. McAllum, M.B. Edin., to Louisa, only daughter of the late Colonel A. H. Cooke, Indian Staff Corps, and of Mrs. Cooke of Queen's-terrace, Sussex-road, Southsea.

TATE—BEETON.—On August 14th, at Streatley Church, Captain Godfrey Tate, I.M.S., to Dorothy, younger daughter of the late Edmund M. Beeton and Mrs. Beeton of Tweenways, Streatley, Berks.

Notes, Short Comments, and Answers to Correspondents.

THE QUESTION OF IMMEDIATE ATTENDANCE.

ON August 15th, Mr. C. C. Becke, the coroner for Northampton, held an inquest into the causes attending the death of a man named Isaacs, aged 34 years. The widow in her evidence stated that on Sunday afternoon her husband had complained of feeling ill. On the Monday he did not go to work. On Tuesday morning at 9 o'clock she communicated with the Medical Institute. The medical man came a few minutes before 6 P.M. He prescribed some medicine which witness went up to the Institute to fetch but her husband died just as she was about to give it to him. Dr. William George Sutherland, the medical man, stated that he had been called to see the deceased on the Tuesday morning. It appears that he was acting as locum-tenent for the regular medical man attached to the Institute. As he was a stranger to Northampton he inadvertently did not get to the deceased's house till between 5 and 6. He considered the deceased to be suffering from catarrh of the stomach and he was collapsed. Dr. Sutherland went on to say that he had made a post-*mortem* examination and found all the abdominal organs healthy except the stomach. The heart was very much enlarged and covered with a layer of fat. The condition could not be diagnosed during life for a certainty. In answer to a juror Dr. Sutherland said he was not told in the morning that the case was urgent. The jury found that death was due to natural causes, but the foreman added "but at the same time the jury express regret at the neglect apparently of the doctor in not going earlier. There might have been a little possibility of doing something for the man." It was stated that Dr. Sutherland had only been in the town for three days and that it was naturally difficult for him to pick up every case. The coroner is reported as saying "He had him on his list and he ought to tick the cases off as he attends them." We cannot quite see what the coroner meant by this remark, for whether the name was ticked off or not it would have made no difference to the time at which Dr. Sutherland arrived. The coroner further remarked that if the relatives had any complaint to make they might make it to the committee of the Institute. We have no knowledge whether they did or did not make such complaint, but in the *Northampton Independent* of August 18th appears the following advertisement on p. 19:—

FRIENDLY SOCIETIES' MEDICAL INSTITUTE.

50, Broad-street, Northampton,
Thursday, August 15th (*sic*), 1906.

We beg to state in connection with the inquest held yesterday on the body of W. E. Isaacs that the *locum tenens* engaged in Dr. Bensley's absence on his annual holiday has been dismissed from his practice at the above Institute.

On behalf of the Committee,
J. J. W. PAGE, *President*,
J. B. PALMER, Secretary.

This friendly society does not seem to be a very just employer. When Dr. Sutherland was summoned in the morning he was not told that there was any urgency in the case. It was no doubt regrettable that this particular case was left until the last, but presumably, seeing the patient's condition, it would have made no difference whether Dr. Sutherland had arrived early or late, and the error by which he arrived late was fully explained. It would be interesting to know what the Friendly Societies' Medical Institute pays its medical men, but we at any rate congratulate Dr. Sutherland upon no longer being its employé.

QUACK ADVERTISING.

LAST week we commented upon the circular of a touting agency which professed to have been given the name of a medical man to whom it wrote. Another correspondent, who is a physician to a well-known hospital in the West of London, has sent us several circulars which he has received from the M. A. Winter Co. of Washington, D.C., North America. The circular quoted is, as will be seen, in the same style as that which we mentioned last week. Our correspondent, who has never acted as agent to any company, was naturally surprised by receiving a long circular letter of which we reproduce the commencement and a few subsequent paragraphs.

> DEAR FRIEND,—Your name has been handed to us by a business concern with whom you have been corresponding as a good party to take up our work in your section. The company speaks in the highest terms of your ability as an agent; therefore we are very anxious that you should work for us. ...... In fact, we believe you are just the right person to push such a good and profitable business as we offer you for all it is worth. ...... By selling this remedy you are building up a trade which will not stop but will go on increasing from year to year, because it becomes a staple article just like sugar or flour.

The remedy in question, which is guaranteed by the vendors to mitigate or remove a great variety of ailments, is "composed of the choicest barks, roots, and herbs." It is put up in boxes, 12 of which can be bought by the agent *for £1 7s. 1d. for resale* to the public at *4s. 2d.* each. The absurdity *of asking* a medical man to sell a quack remedy of unknown composition, guaranteed to give relief in a multitude *of diseases, might serve* a *purpose* in a jest-book but not elsewhere. The truth is that both the M. A. Winter Co. and its wonderful medicines are unworthy of serious consideration.

APPLIANCES FOR RESCUE WORK IN MINE ACCIDENTS.

Rescue parties in mine accidents are very often exposed to the dangers incidental to an irrespirable atmosphere, and firemen are similarly liable *to be overcome by smoke* and *acrid* or poisonous fumes. In The Lancet *of* August 13th, 1904, p. 477, we described an apparatus devised by Dr. Guglielminetti of Paris for the purpose of reducing these risks. *It consisted principally of a helmet* something like that of a diving dress but made *of* aluminium instead of copper; a cylinder of compressed oxygen carried on the back; a vessel containing *trays of caustic* potash *to absorb* the respiratory carbon dioxide; and a flexible breathing bag filled with ordinary atmospheric air, the nitrogen of which remained unchanged, while the oxygen *was renewed from* the cylinder and the carbon dioxide removed by the caustic potash. A man *can* easily carry enough oxygen to last for 30 minutes. Various contrivances for the same purpose have been *introduced by inventors such as Fleuss* and more recently by Herr Meyer of a Westphalian colliery, but they are all on very much the same lines. A few of them are enumerated in The Lancet of *Feb. 17th, 1906*, p. *488. Several years ago, however*, an inventor residing in the north of England brought to the office of The Lancet a *loose overcoat of air-proof material* with a lining of the same; this when inflated with *ordinary air by a bellows* held a supply which could be inhaled with a face-piece and was sufficient to last for a good while. In the terrible disaster which occurred at the Courrières collieries in the *north-east of France early* in the present year Herr Meyer having brought men and appliances from Westphalia was able to do important *rescue* work. The Westphalian exploring party carries a telephone by means of which communication is maintained with those who are in places of safety. Mr. Sydney F. Walker, writing in the New York *Electrical Review* of August 4th, on the general subject *of rescue after* mine accidents, says that there is an ever present danger of the collapse of the explorer partly from fatigue due to the weight of the apparatus carried and the bad state of the roadways after an explosion, and partly from the gradual vitiation of the air which he breathes owing to the slow removal of the carbon *dioxide by* the caustic potash. Mr. Walker therefore suggests that the bodily condition of the explorer *who carries* a telephone might always be known at the safety station in his rear if a microphone were placed on some convenient artery and connected with a telephone at the safety station, where a surgeon *might infer* the condition of the distant explorer from the sounds heard in the telephone. A somewhat similar arrangement might also be connected to some part of the explorer's chest, so that the laboured breathing which accompanies exhaustion, whether *from* exertion or from the presence of much carbon dioxide in the inhaled air, might also be read at the pit bottom.

HARVEST BUGS.

To the Editors of The Lancet.

Sirs,—"L.R.C.P." should try commercial carbolic acid as a general disinfectant. *Powdered borax* may also be dusted here and there on the surface of the body. Menthol dissolved in petrosol, spirit, or oil, applied by spray or on cotton-wool, will give instant *relief to irritation.*

I am, Sirs, yours faithfully,

Annfield Plain, August 18th, 1906. W. G. Pretsell.

MARGARINE AND PREJUDICE.

There is after all a good deal in a name or the lay mind would not regard with so much apparent prejudice that excellent and wholesome substitute for butter—margarine. *One worthy London* alderman *seems to* think that it is no better than, say, train oil, for on imposing very properly a fine on a certain catering company last week for selling butter which was not in *fact butter but margarine*, he was induced to reduce the maximum penalty because the defendant's solicitor had given an assurance that margarine would not be used again *even for cooking purposes.* Now, the Sale of Food and Drugs Act does not require that butter and nothing but butter should be used for cooking purposes, and there is no reason why it should do so. *It is*, in fact, possible *that margarine* is better for some cooking purposes than butter. Margarine is an excellent and palatable fat food and its process of manufacture is calculated to render it less open to bacteriological suspicions than butter. Margarine is not, and never can be, butter, any more than apples can be peaches, but that is no reason why apples *should* not be perfectly good food material.

A LIST OF OFFICIAL *CHEMICAL* APPOINTMENTS.

Under the direction of the *Council* of the Institute of Chemistry Mr. Richard B. Pilcher, the secretary of the Institute, has compiled a list of the official chemical appointments held in Great Britain and Ireland, *in India*, and the colonies. In some ways the book has its prototype in the Medical Directory, while it serves to indicate the increasing appreciation of chemical investigation by departments *of* State, Colonial governments, local authorities, and *public* institutions throughout the British empire. It includes a very complete list of *the names of the professors* and teachers of chemistry in universities, colleges, and technical schools, and also the names of the analysts appointed under the provisions of the Sale of Food and Drugs Act. *We believe* that the publication is the first of its kind connected with the practice of professional chemistry, and though intended primarily for the use of consulting and analytical *chemists it will* obviously be useful for reference to public authorities, and indeed to all interested in the applications of chemistry to State matters and in the promotion of higher *education in chemical* science.

THE GERMAN LANGUAGE AND MEDICAL MEN.

To the Editors of The Lancet.

Sirs,—In the Annotations column of The Lancet of August 18th you refer to the small number of medical men who are able to read German medical *books. Dr. Fiedler*, professor of German in the University of Birmingham, with the assistance of his colleague, *Mr.* Sanbuch, has recently brought out an excellent little book designed to teach busy men *enough* German to enable them to keep abreast of German scientific literature. The plan of the work is simple and practical and the price is small—2s. *6d.*

I am, Sirs, yours faithfully,

Birmingham, August 20th, 1906. Arthur Loxton.

THE TREATMENT OF FŒTID FEET WITH CHROMIC ACID.

Dr. Sabouraud, in the *Journal de Pharmacie et de Chimie* of July 16th, recommends the use of a 4 per cent. solution of crystals of chromic acid in distilled water in cases of fœtid perspiration of the feet. The lotion is applied briskly by means of a plug of cotton-wool, care being taken that the liquid thoroughly penetrates between and under the toes. The treatment should be repeated daily for a few days, then every second day, every third day, until finally one application a week is usually sufficient to complete the cure. Dr. Sabouraud states that unpleasant odours of the feet rapidly disappear under this treatment and that the effect remains for a considerable time. The lotion should never be applied twice on the same day owing to the risk of producing an erythematous eruption lasting several days.

THE LAW, THE MEDICAL MAN, AND THE MOTHER.

To the Editors of The Lancet.

Sirs,—I was called upon *one* night recently by the usual constable with the usual slip of paper stating that a male child had been found deserted, &c., and asking if I could throw any light on the subject from any confinements *I had* attended lately. He could not say whether the child was found living or dead.

As a fact I had attended no labours for months, and said so; but not being busy at the time, and the man being of intelligence, I discussed with him the ethical question of giving or withholding such information. Inviolable confidence between practitioner and patient was the *line I took, and* take; whilst one's duty as a citizen was his standpoint, a duty, he contended, that is paramount to all other considerations.

The point is interesting, and not infrequently arises in general practice.

I am, Sirs, yours faithfully,

M.B. Lond.

August 14th, 1906.

* * *

Lex.—Our correspondent is entitled to deduct the cost of feeding the patients, whether the diet is special or otherwise; but he is not entitled to deduct anything for medical attendance.

Chantry-road.—Our correspondent who wrote from this address but who omitted to sign his name is advised to consult the public analyst for his district.

Erratum.—Mr. J. Lionel Stretton writes:—In my description of Two Unique Congenital Deformities in the Abdomen of the Same Patient reported in your issue of August 18th, p. 440, there is an obvious error. "Cardiac end of the stomach" should read "*pyloric end.*"

Communications not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1906, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1906 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *Leeds and Yorkshire Mercury, Liverpool Courier, Northern Whig, Telegraph, Daily News, Morning Post, Daily Mail, Evening Express (Liverpool), Morning Leader, Globe, Bristol Times, Elgin Chronicle, Bristol Mercury, Westminster Gazette, Birmingham Post, Hampshire Advertiser, Southampton Echo, Wolverhampton Midland Express, Newcastle Chronicle, Herts Mercury, Scientific American, Literary Digest, &c.*

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 1, 1906.

An Address to Students.

ONCE again it is our duty to speak words of welcome to those who are for the first time joining the ranks of medicine; and although to a certain extent what we have to say must be what we have said before—for it is to be remembered that we have preached from the same general texts for over 80 years—we are pleased to find that each year brings its special message to the medical practitioner and to the man who is embarking upon a medical career. The fact that this is so shows that the profession of medicine is in no way a stereotyped affair, for now one thing and now another thing comes into prominence as the essential point of the year, the association between the profession of medicine and the varying and various needs of the public being in this way demonstrated. A war pointedly attracts our attention to the organisation of military medical defence; a trans-Atlantic scientific congress, a meeting of the British Association in South Africa, or a historic pageant in India draws our gaze to different regions of our empire beyond the seas, and reminds us that the principles by which that empire is governed resemble in no superficial way the principles of medical practice. Just as a multiformity of legislation is required to deal with a multiformity of social conditions, so an elaborate scheme of therapeutic processes has been devised to meet groups and subdivisions of disease; but the essentials of justice remain the same and so do the ends and aims of medicine.

The difficult question of medical education seems to us at the present moment to be the one that most presses for settlement, and no student should commence his career without having some idea of the curriculum that lies before him, and without knowing why he is compelled to pass certain tests. Disorderly as the educational path of the medical student is—and we have only to refer to the masses of information which follow under the headings of all the different medical schools of the kingdom for justification of the uncomplimentary epithet—yet the track is clearly marked out and the tests that lie before him are well-intentioned and purposeful. He should start on his way with an idea of what is required of *him*. Our words are naturally directed to all medical students, British or Colonial, metropolitan or provincial, but inasmuch as the conventional course of the medical student varies in large things and small according to the locality where he studies, the message will not always apply to all of them. Let us begin with the London medical students, still so numerous although their numbers have gone down, and still enjoying such enormous privileges though weighted by a correspondingly heavy handicap. The privileges of the London medical student are obvious. London is not only the capital of this empire but it is a truly world capital in a way and to an extent that, say, Paris and New York are not. If, as would appear to be the indisputable case, medicine and surgery can be best learned where men and women are crowded together in the greatest density, displaying the most numerous types of disease and the most complicated forms of social inter-relation, then it follows that London possesses the qualifications for the provision of the finest medical education in the world. As a writer in THE LANCET said last year, when commenting upon the fact that the number of students at the London Medical Schools was rapidly dwindling year by year:—

> By so much as the work done in the wards and out-patient departments of the London hospitals is not utilised for educational purposes, by so much is our country placed at a disadvantage compared to others—we are wasting our opportunities. The world is the poorer and Great Britain is especially the poorer. The advantages of living in London, and the field that is offered by London for the observation of disease, cannot have escaped the attention of the student or his parents. A huge seaport, the seat of a court and a Government, a teeming industrial centre finding employment for tens of thousands of operatives, a fashion and a pleasure capital, a focus around which 20 residential cities are more or less loosely grouped, and the money exchange of civilisation—that is London, and such a city, or rather such a congeries of cities, must have within its ill-defined ramparts examples of all sorts and conditions of physical ill. Before the student of disease would turn his back upon the opportunities thus offered to him he must feel that he would suffer in London from disabilities so serious as to annul the benefits.

It is the disabilities here referred to which we would have the medical student realise from the first, for with early industry and perseverance he may make light of them.

The London medical students are less numerous than they used to be because medical education in London is suffering from gravely anomalous conditions. Several attempts at restoring order have been made, and some of them have been made with success, but none the less much remains to be done before full advantage will be taken of the wonderful pathological material offered by the metropolis. The London medical student cannot obtain an M.D. degree upon the same terms as can the student of one of the Scottish or Irish or provincial universities. This is now a well-known fact to both students and parents and cannot be without its influence upon them. Again, the presence of a dozen different competitive medical centres in London is a source of weakness. In days not long gone by medical education implied no real acquaintance with allied sciences, and no practical skill in their application was demanded of the student before his actual professional training commenced. The machinery for medical education was then so simple that a number of centres was rather to be encouraged than not, for healthy rivalry was produced by them. But when the cost of medical education became very heavy, when new laboratories had to be built, when many demonstrators and lecturers were required, it became manifest that in London the plan of numerous rival schools was disastrously uneconomical. A partial attempt has been made now to meet this evil, and many able men, devoted to the cause of medicine and seeing in anything that produces the desertion

Agent for the Advertisement Department in France—J. ASTIER, 51, Rue Bapts, Asnières, Paris.

Apothecaries are not in professional opinion entitled to style themselves "doctor," though the public will not allow them to describe themselves otherwise. This is extremely galling for the diplomate, as the public cannot understand his position and may regard him as an inferior man. Hence a never-ending subject of discussion among medical men, and hence also a position by which the new medical student should take warning. The only way to avoid disabilities, under which, at any rate, some members of the medical profession feel that they suffer by not possessing a medical degree, is to keep the attainment of such a degree steadily before the eye as the natural end to the student's curriculum. We know well that many men, so many as to form a substantial majority of the medical practitioners of this country, possess the pass titles of a corporation and enjoy every whit as good a position, scientifically and socially, as their colleagues who happen to be medical graduates; but the number of medical graduates is rapidly increasing and the new student should make up his mind not to be in the position that many diplomates are beginning to find unsatisfactory. This advice must come harder to the London student than to students in the new provincial universities, or in Edinburgh, where medical education is more concentrated and orderly, and where the medical degree is the natural ending to the career of all hard-working students. But all medical students alike should strive for a medical degree from the beginning of their medical careers, and the hardships of the London student may turn out blessings in disguise if the curriculum is steadily persevered with.

And this brings us to the second main lesson that we wish to impress upon the medical student of to-day. Not only is medical education in a fluctuating condition but the social and material position of the medical man is also not so stable as it was. Consequently, it cannot be too firmly impressed upon the medical student that in his preliminary education and general culture will lie a great part of his future strength. It has been pointed out recently by more than one writer that while the scientific equipment of the medical man of to-day differs in countless respects from that of his grandfather, the expansion of learning that has taken place in medicine has been taking place in all other branches of knowledge, with the result that the status of the medical man has been somewhat altered. He is no longer a member of one of three learned bodies, keeping within the *ring-fence* of their curriculum the academic and scientific culture of the nation. The nation as a whole is becoming educated, and a university training is now quite frequent in walks of life where recently it was regarded as useless if not detrimental to a man's material progress. The result is that the medical man, if he is to be certain of the consideration of his patients, if he is to be esteemed as he formerly was by the public, must take pains to acquire a sound preliminary training. Time spent over a difficult matriculation is not wasted. The student has a right to expect that his educational course should be a straightforward one and that facilities will be forthcoming for him to obtain the learning, possession of which he has afterwards to prove in examination. But he must not nowadays expect to be admitted to the rolls of the profession under any simple tests; all that can be done for him is to make it easy for him to get proper instruction for those tests. The student must be prepared to undergo stringent scrutiny before admission to the roll of his profession, and he will find a premium set upon his evidences of general culture, because it is recognised that he cannot take his proper place among the educated classes of the public simply by the light of technical equipment. And it is especially important that medical men should be well regarded of the public, for it is to the public that the medical profession has to look for the redress of its manifest grievances.

There are at the present moment, we all know, many hardships existent in medical life. There is no reason to suppose that hardships will not always exist, and when those that now play such a prominent part in the life of medical men do not exist others will quite possibly take their place. But in spite of this we would urge the recruits who are now joining our ranks not to pay too much attention to the cry of the pessimist. As a medical practitioner, in whatever section of the profession his duties call him, he will have to work hard and very often, more often than not, his reward will not be commensurate with the amount of work that he does. But some of the loudest cries from within the ranks of the medical profession against medical life are not quite reasonable. *For example*, there is no justification whatever for saying that the ranks of the medical profession are grossly overcrowded. The ratio of medical men to the population is now very much what it was 40 or 50 years ago, and we are at no disadvantage in the matter compared with other countries. Members of the medical profession are not evenly distributed among the population, and the acute cases of rivalry are due not to the fact that in the bulk there are too many medical men to the population but to the fact that too many of them desire to do the same kind of work. Again, we are told that medical aid associations have ruined the medical practitioner. Undoubtedly, in many places clubs have exploited their medical officers and grave hardships have followed, but it is our belief that the worst mischief here is over and that the public is beginning to perceive that the resistance made by medical men to the exactions of medical aid associations is legitimate: in which case the future exertions of ignorant persons directed to the exploiting of scientific work are doomed to failure. Hospital abuse, again, is a very real grievance to the medical practitioner as well as to the genuine sick poor, but there are signs of a healthy feeling in the matter. The idea is now certainly abroad among hospital authorities that it is necessary to watch vigilantly over the class of cases offering themselves for treatment. The hospitals owe it to the really sick that their ministrations should not be exploited by trivialities, and they owe it to the public that their wards should not be gratuitously used by patients who are able to pay adequate medical fees in accordance with the usual, and by no means exorbitant, scale in this country. Now that this sentiment has got abroad we may hope that the day is not far distant when the out-patient departments of the hospitals will be recognised by the public as the poor man's consulting-room, as the place where he goes to get a consultant of London by the medical student a grave disaster for the cause of science, are collaborating to place the medical education of London upon a more satisfactory basis. We may look forward confidently to the day when the scientific courses ancillary to the medical profession may be taken out in London at two or three centres, leaving the various medical schools to provide for the student, when he has reached his professional classes, that clinical material which is unrivalled in London and without which no scheme of preparatory scientific work is of any use. A certain amount of centralisation has already taken place, with a manifest saving of time, labour, and money, and this is a direction in which reform may be expected. The University of London is also aware of the necessity of so arranging and codifying the medical course that the able and industrious medical student, having before him a straight even if an arduous journey, will arrive by the usual amount of application at a medical degree as the natural termination of his labours. There will necessarily be differences of opinion as to the amount of facility that the University should offer. No one desires to see the standard of the famous London degree lowered, yet no one can fail to appreciate that many admirable students have missed obtaining that degree owing not so much to the stringency of the professional tests as to the unnecessary multiplication of earlier examinations, the vagueness of the schedules for these examinations, and the want of provision of adequate assistance at some of the medical centres. Reform of all these things is in the air, but much remains that requires amendment, so that it must be to some extent the task of the London student to lay out for himself as orderly a career as possible, in doing which we urge him to determine to obtain the degree of his university.

Considering now medical education generally, undoubtedly it is in a transition condition, and wherever we have to deal with transition conditions some class or other undergoes hardship. For example, our highways were constructed, as befitted those of an agricultural country, for pedestrians, for horsemen, for transit by wagons of food-stuffs, and for the passage of a certain number of lighter horse-drawn carriages. Violent transition in our methods of traffic has ensued and our highways are no longer adequate or suitable for the purposes to which they are put. The motor car, whether driven for pleasure or commercial purposes, has seized the roads for which it is unfitted, and immediately the gravest hardships have followed for those who live abutting on the roads. Their homes may be well-nigh ruined, their business may perish, and material and mental damage hardly to be appreciated may be their lot, yet he would be a bold man who should say that, despite these obvious and valid objections to the use of motor traffic as we now see it, the motor will not play a part in a new and prosperous era for country districts. If this be so, the only course open for the present sufferers is to range themselves as quickly as possible on the side of the new *régime*. Another example, and one more distinctly germane to medical affairs, of the cruelty that follows upon social transition, though that transition may have been designed as reform, is afforded by the case of unqualified assistants. The General Medical Council recently abolished with little warning and little ceremony all unqualified medical assistants. These men formed a large class and played an important part in the scheme of work of the general practitioners of the last century. When they were swept away a number of men, some of them good, useful, and worthy citizens, were suddenly deprived of all means of livelihood, while many members of the medical profession were embarrassed by the loss of valuable coöperators in the routine of their work. A premium was placed upon the assistance of the newly qualified medical man who could and did demand a higher salary than the unqualified assistant, but who in many directions was unable to help his principal in the manner that made the unqualified practitioner so useful. Many unqualified practitioners were, for example, skilled obstetricians, while few young men who have recently obtained their degrees or diplomas can be thus described. Here we have hardship to many general practitioners and distinct hardship to all the class of unqualified practitioners, and for the time being a premium put upon the services of inexperienced persons. Upon its face the situation was unjust, yet nobody who has studied medical politics at all has the least doubt that the cause of medicine was properly served by the abolition of the unqualified practitioner. He was an anomaly and in the cause of progress he ceased to exist, but the process of transition was attended by distinct cruelty.

The medical man of the present day, whether in London or elsewhere, may have to suffer from the transition condition of medical education and the altering position of the medical man towards the public. The General Medical Council has been debating the state of the medical curriculum for the past two sessions; it has been found overloaded and unpractical in some directions and deficient in others. The student admittedly has no time in which to read all his subjects thoroughly, yet the fifth year of his course, which was to have been devoted to clinical work, is spent by most students in getting up book-work. This position will not remain unchanged, but what the medical student must understand is that there will be no lightening of his labours by the lowering of standards. He cannot too soon range himself on the side of progress. To give this advice to the unfortunate holder of a long lease of a half-ruined frontage is, of course, idle. He cannot go a-motoring himself because the developments of the motor industry have deprived him of money; others will benefit by the warning which he supplies—he apparently cannot be helped. But the medical student who has just joined a school is still in time to anticipate the directions in which success may come to him from new developments in the profession of medicine, as well as the directions in which he must be on his guard. And the first advice that we give to the medical student—advice that should be given to him by all parents or deans of medical schools—is to work for a medical degree. For the time being this is the only solution for the medical man of the vexed question as to who has a right to the title of "doctor." It is an embarrassing fact that only those who graduate in medicine at one of the universities bear by academic right the style which is popularly granted to all medical men—viz., the title of "doctor." The diplomates of the Royal Colleges and the Licentiates of the Societies of

THE STUDENT'S LIBRARY.

WE offer below some suggestions for the benefit of the medical student as to the books which he is likely to find most useful in the course of preparation for his examinations. We have not found it necessary this year to make any extensive revision of the lists of books which we recommend; but the columns of THE LANCET which are devoted each week to the reviewing of new text-books have during the year contained notices of many works that can be used in substitution for, or in supplement of, those that we mention.

The student has to remember that there are two objects which he should have in view: the first, which is usually looked upon as the more urgent, is the passing of the various examinations which are necessary for the degree or diploma he desires to obtain. The other object is, however, of more importance ultimately, and this is the attainment of a thorough knowledge of his profession so that he may practise it to the benefit alike of his patients and himself. The books which are most suitable for the second object are not necessarily those which would afford most assistance in attaining the first. The examinations, however, must have the prominent place while he is yet a student, for until he has surmounted these obstacles he is entirely precluded from the practice of his profession. In choosing books for a particular examination the student must avoid both reading too little and reading too much. The greater danger lies, perhaps, in reading too widely. Many students dip into many books and fail to master any. The student should recognise the scope of his examination and should first endeavour to limit his reading to the required standing. When, however, he has made himself master of that portion of the subject which the regulations of the examination require he may go farther. A book may be very useful or even necessary for one examination and useless for another of a different standard, and if useless it is really harmful, for its perusal will take up time which might be more usefully employed. There is every year an increasing difficulty for us to pick out individual treatises, for the output of volumes from the medical press has increased enormously; but, on the other hand, it is every year less and less important which particular work the student selects. Only a few years ago he was limited to the medical treatises appearing in the British Isles, but now in addition he has the very large supply of works from the other side of the Atlantic, for several American publishing houses have established branches in this country from which they are putting out works of the highest order From these three things—the large supply of text-books, their excellent and authoritative nature, and the addition of many valuable American works to our library—arises a great difficulty for anyone who should attempt to suggest to the student what should and what should not be the book he ought to buy. In nearly every branch of professional knowledge there is a very wide choice, and all that those most familiar with contemporary medical literature can do is to offer the student some general guidance.

BOOKS RECOMMENDED FOR THE DOUBLE QUALIFICATION OF THE ENGLISH ROYAL COLLEGES.

In the list which appears below we have again, as in previous years, taken the examinations for the *double diplomas* of the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England as the type of the tests which every student works to pass. He may not do so much and he may do *more*; the above-mentioned qualifications are good and representative ones and are sought by a very great number of medical men whether they proceed to graduate at a university or not. Our advice given in the address to students is that every student should now strive for a medical degree and the multiplication of local universities has begun to lessen to some extent the number of men competing for the diplomas of the different Royal Colleges. But the great number of candidates for the degrees of the provincial universities still pass the examining boards of the corporations first, and very often must find that the tests that they have already undergone are as severe as any they are later asked to undergo. It is unnecessary, and indeed impossible, to make any attempt to suggest text-books to be read for these particular medical degrees. The lecturers in the various faculties at the universities will suggest to their students the manuals to be read and, having regard to the fact that the majority of their students still desire to belong to a corporation as well as to a university, it is probable that the books recommended as necessary for instruction on the general subjects will in the main be the same as we now set down.

The following are the text-books recommended by the consensus of opinion of a representative group of London teachers for the examinations of the London Conjoint qualification, the list having been carefully revised this year:—

FIRST EXAMINATION.

Chemistry.—LUFF'S *Chemistry* (Cassell, 7*s.* 6*d.*).—This book was written with a view to this examination and contains exactly the right material.—ATTFIELD'S *Chemistry* (Gurney and Jackson, 15*s.*) is also recommended, but is rather more elaborate.—CORBIN and STEWART'S *A Handbook of Physics and Chemistry* (J. & A. Churchill, 6*s.* 6*d.*) is excellently adapted to the requirements of this examination.

Physics.—DANIELL'S *Physics* (Macmillan and Co., Limited, 4*s.* 6*d.*).—ALDOUS'S *Physics* (Macmillan and Co., Limited, 7*s.* 6*d.*). The student will only require selections which should be made in accordance with the advice of his teachers.

Pharmacy.—HALE WHITE'S *Materia Medica* (J. & A. Churchill, 7*s.* 6*d*).—*The Science and Art of Prescribing*, by E. H. COLBECK and A. CHAPLIN (Kimpton, 5*s.* net), is a valuable little introduction to the practical application of materia medica and will be useful to the student when he reaches the wards.—*Practical Pharmacy and Prescribing*, by JAMES CALVERT (H. K. Lewis, 4*s.* 6*d.*), is a trustworthy notebook which is in use by the students at St. Bartholomew's Hospital.

Biology.—P. CHALMERS MITCHELL'S *Outlines of Biology* (Methuen, 6*s.*).—The book was written with a view to this examination, but it is frankly only an introduction. Still, the subject at this examination is a very limited one.

SECOND EXAMINATION.

Anatomy.—GRAY'S *Anatomy* (Longman's, 32*s.* net).—QUAIN'S *Anatomy* (Longmans, in nine parts at different prices).—MORRIS'S *Anatomy* (J. & A. Churchill, 30*s.* net).—The first of these treatises is sufficient by itself, while the article in it upon osteology is unequalled. The books of QUAIN and MORRIS contain matter that is not essential for the examination under consideration, but all who aspire to the higher examinations should have and read one of them. The same may be said for the *Manual of Practical Anatomy*, by the late Professor ALFRED HUGHES and Dr. ARTHUR KEITH (J. & A. Churchill, in three parts, 29*s.* 6*d.*).

Physiology.—HALLIBURTON'S *Kirkes' Physiology*, sixth (being the nineteenth edition of *Kirkes' Physiology*) edition (J. Murray, 14*s.*).—FOSTER'S *Physiology* is probably the best text-book in English and written in a good literary style, but it does not supply the medical student with sufficient cut-and-dried answers to questions which are sure to be set him at this examination. HALLIBURTON'S *Kirkes* is therefore the book to be recommended for the average student, but by all means let him enlarge his knowledge by reading FOSTER'S book if he finds that he can swim in deeper water.—HALLIBURTON'S *Essentials of Chemical Physiology* (Longmans, 7*s.* 6*d.*).—SCHÄFER'S surgeon's or physician's view on his case when his medical man or the medical officer of his provident dispensary desires a further opinion on his case. All these questions may seem far removed from the medical student's sphere, but they will soon press upon him and he cannot familiarise himself with professional problems too soon.

Our message, then, to the medical student is to work from the first for honours, and if in doing so he finds that he has to learn a good many things the immediate utility of which he does not perceive he must take it for granted that the more general his education the more ready will the public be to accept him as an adviser, and the more sympathetic and capable adviser will he be. It is to the public, as education permeates downwards, that the medical profession has to look for that general esteem of scientific work which alone will redress our professional grievances, and it is necessary that the public should see in us an exceptionally highly educated body of men.

THE DEVELOPMENTS OF PATHOLOGY.

THE institution of laboratories as an aid to clinical work in private and hospital practice is a result of the general development of pathological research which has yielded such valuable information during recent years. Since the year 1882, when Professor Koch demonstrated the pathogenic organism of tuberculosis, the importance of laboratory investigation in connexion with purely clinical work has been gradually made manifest, until at the present time certain pathological procedures have become matters of routine in medical practice. At first the mere detection of micro-organisms in sputum or in the organs of the body after death occupied the attention of those observers who were gradually developing the new science of bacteriology. In the wards and in private practice the ordinary examinations of urine were made; occasionally the blood was examined in regard to the amount of hæmoglobin contained and the numbers of red and white corpuscles were duly counted, but so far no more detailed laboratory work was undertaken as part of the ordinary routine of therapeutics. Now, however, the various processes which have been introduced as an aid to diagnosis are numerous and complicated and can only be accurately carried out after careful instruction, while trustworthy conclusions can only be arrived at after long experience. In order to perform the tests founded on bacteriological and pathological facts laboratories specially fitted are essential. Certain of the more simple procedures, such as the detection of tubercle bacilli in the sputum or the examination of urine for albumin and sugar, can, of course, be carried out by every practitioner possessed of a good microscope and the necessary reagents. On the other hand, the estimation of opsonic indices, the performance of the Widal reaction for typhoid fever, the culture test for diphtheria, the differential estimation of the various forms of red and white blood corpuscles, as well as the more complicated processes of chemical analysis, can only be conducted in well-appointed laboratories. The medical curriculum is, of course, far more involved than it was formerly, and considering the multiplicity of subjects in which the student is examined, the question naturally arises, How far is it incumbent upon him to make a practical study of the more advanced of the developments of clinical pathology to which we have alluded? That he should attend a course of lectures and demonstrations on bacteriology is absolutely necessary; he must acquire personal knowledge of the characters and properties of the more common pathogenic micro-organisms. We think also that he should see the more elaborate processes carried out by the lecturer, such as the estimation of the opsonic index and the methods of staining employed in the differentiation of the various forms of leucocytes; but that he should be able to perfect himself in these measures cannot be expected, and he has a right to anticipate that examiners will not demand such accomplishments of him. Prolonged practice and experience are necessary before difficult and delicate laboratory work can be performed properly, and trustworthy deductions drawn from it. The student has not the time to devote to acquiring the necessary experience, and secondly, even if he had the time in subsequent practice, in the majority of instances he would not have the necessary appliances at his command. All the students who wish to hold resident appointments might well be asked to attend for a certain time in the hospital laboratory, for without at any rate some first-hand knowledge of the work conducted therein they will not be adequate assistants to their chiefs and will lose many of the benefits of their appointments. We find, therefore, that early in the student's curriculum there will naturally be differentiation in the course of studies pursued, some students leaning towards laboratory work by inclination, or being persuaded to go thoroughly into such work because of the advantages derived from it; others only doing so much as is necessary for the passing of their examinations. But we have impressed upon the student in our opening address this year that he should keep his eye from the beginning of his career upon the obtaining of a medical degree, and for this reason we remind those who would as far as possible avoid laboratory work that a certain familiarity with the *rationale* of modern adjuncts to diagnosis and treatment will be expected of all who are taking out an honours course.

But there is no gainsaying that there is now room for a body of workers devoted entirely, or almost entirely, to laboratory methods. The special training required, the closeness and minuteness of their studies, and the familiarity with practical detail exacted of them make it impossible that these observers should keep at the same time in touch with clinical medicine, while the average medical student cannot pursue such developments and work at the same time for his pass examinations In order to obtain the fullest value from the pathological laboratory the services of experts are required, which means that certain members of the medical profession must devote themselves entirely to this branch of science whilst the others in tending the sick obtain the advantage of laboratory experience. Combination between the labour of each class is, of course, essential. We must not arrive at conclusions purely by experiments *in vitro*, and results obtained in the laboratory must therefore be constantly compared with observations recorded in the wards and in the post-mortem room. Upon the worker in pathological laboratories there devolves the testing, and in some instances preparing, the serums, vaccines, and other preparations now used in the treatment of disease. The gelatin treatment of aneurysm, for instance, is dependent for its safety on the proper sterilisation of the gelatin, and this can only be effectually carried out in well-appointed laboratories. The workers in the laboratories connected with large hospitals have abundant opportunities of obtaining and examining the products of bacterial invasions and most valuable results may be looked for in the future from such observations. It is obvious once more that such investigations can be only carried out adequately by those men who have devoted much thought to this special branch of science, and who therefore have not the time, as a rule, to undertake the duties of the ordinary practice of their profession. The importance of such inquiries cannot be exaggerated; in the laboratories of clinical and pathological research we possess one of the most valuable aids to the diagnosis and treatment of disease introduced in modern times.

In recognition of the part that scientific pathology now plays in assisting the practitioner in the daily routine of his duties, laboratories have been established in most of the large towns to which specimens of all kinds may be sent for examination and results speedily obtained. With these establishments always ready to aid him the practitioner can depend on trustworthy reports being at once afforded him. Consequently, as we have suggested above, the student need not feel it incumbent upon himself to devote such an amount of time to laboratory methods as is required to obtain perfection of technique. Some knowledge of bacteriology and cytology, however, will considerably add to the interest of his observations when in the future he is engaged in the actual practice of his profession, and we therefore would advise him to take every opportunity of noting the reports emanating from the laboratory attached to his hospital, and also to attend demonstrations which may be given on the subject.

(Young J. Pentland, *two* volumes, vol. i., 10*s.* 6*d.*; vol. ii., 12*s.* 6*d.*). Professor CUNNINGHAM has also published a splendid *Text-book of Anatomy* (Young J. Pentland, 1903, 31*s.* 6*d.* net) written by himself and nine other competent contributors. The book is profusely illustrated with original drawings and much in it which deals with the topographical relations of the viscera departs considerably from convention. This is a book from which the able student can derive much suggestive information. We may also mention MACALISTER'S *Human Anatomy* (Griffin, 36*s.*). For both these examinations STEWART'S *Physiology*, fourth edition (Baillière, Tindall, and Cox, 15*s.*), or FOSTER'S *Physiology* (Macmillan and Co., Limited, in four parts, 10*s.* 6*d.* each, and appendix, 7*s.* 6*d.*) should be read.

For the M.D. in medicine of the University of London and for the Membership of the Royal College of Physicians of London we would recommend the following books. For the general foundation the student cannot do better than read FAGGE'S *Medicine*, edited by PYE-SMITH (Churchill, fourth edition, two vols., 42*s.*). This may be supplemented by CLIFFORD ALLBUTT'S *System of Medicine* (in eight volumes, sold separately 25*s.* net each), which contains a number of valuable monographs, and SAVILL'S *System of Clinical Medicine*, a very original work. It is also advisable to read special works, such as POWELL'S *Diseases of the Lungs and Pleura* (Lewis, 18*s.*) or WEST'S *Diseases of the Organs of Respiration* (Griffin, 36*s.*); GOWERS'S *Diseases of the Nervous System* (J. & A. Churchill, vol. i., 16*s.*; vol ii., 20*s.*); BABCOCK'S *Diseases of the Heart* (Appleton, 25*s.*); CROCKER'S *Diseases of the Skin* (Lewis, 28*s.*); VON JAKSCH'S *Clinical Diagnosis* (Griffin, 24*s.*); JUDSON BURY'S *Clinical Medicine* (Griffin, 21*s.*); and SIDNEY MARTIN'S *General Pathology*. For the higher examinations a sound knowledge of bacteriology is needed. STERNBERG'S *Bacteriology* (Churchill, 26*s.*), HEWLETT'S *Bacteriology* (Churchill, 12*s.* 6*d.*), or MUIR and RITCHIE'S *Bacteriology* (Pentland, 12*s.* 6*d.*) will be sufficient. For all these higher examinations it is important that the candidate should be acquainted with the current literature of the subject which has not yet found its way into the text-books. For this current literature he must turn to the pages of THE LANCET and other medical journals. The degree of Doctor of Medicine in the University of London can also only be taken in pathology, mental diseases, midwifery and diseases of women, and State medicine. In each speciality a distinctly high order of knowledge is expected and exacted.

For the examination for the M S. London and for the final F.R.C.S. it is of the greatest importance that the student should remember that his anatomical knowledge must be as extensive and thorough as it was at his previous steps. The student will be already furnished with a good general knowledge of surgery, but it is necessary for him to read a general treatise on the subject, such as TREVES'S *System of Surgery* (Cassell, 48*s.*), TILLMANN'S *Surgery* (Kimpton, 63*s.*), *The International Text-Book of Surgery*, edited by PEARCE GOULD and WARREN (Saunders, two vols., 42*s.*), or KEEN and WHITE'S *Surgery* (Saunders, two vols., 30*s.*). It is also very desirable that he should read some monographs. We have on previous occasions recommended many of the following: BLAND SUTTON on *Tumours* (Cassell, 21*s.*), TREVES on *Intestinal Obstruction* (Cassell, 21*s.*), TUBBY on *Deformities* (Macmillan, 17*s.*), MORRIS on *Surgical Diseases of the Kidney and Ureter* (Cassell, 42*s.*), HOWARD MARSH on *Diseases of the Joints* (Cassell, 12*s.* 6*d.*), and BUTLIN and SPENCER on *Diseases of the Tongue* (Cassell, 21*s.*). Our reviews during the past year and the advice of teachers and lecturers will enable the student to add to this list. A more advanced treatise on operative surgery than that recommended for the Conjoint Examination is also needed, and either JACOBSON and STEWARD'S *Operations of Surgery* (Churchill, 42*s.*) or TREVES and HUTCHINSON'S *Operative Surgery* (Cassell, 42*s.*) will be perfectly satisfactory.

RECENT MEDICAL LITERATURE.

In drawing attention to some of the more interesting and important publications of the year we do not attempt in the course of a few brief remarks to furnish a substitute for detailed criticism. The books mentioned have all been noticed in our own columns and in those of our contemporaries during the past 12 months, and the reasons why we think it right to give them further mention appear in our reviews.

In medicine during the year we have to chronicle the issue of new editions of two excellent text-books. Dr. F. T. ROBERTS'S *Theory and Practice of Medicine* makes its appearance in a tenth edition, a fact which proclaims the book one of the best text-books of the day. The remarks on contagion and infection have been completely remodelled in view of the great advances made in bacteriology since the last edition, and the section on malaria has been entirely rewritten—in short, every pains has been taken to provide a modern and comprehensive manual. Dr. T. K. MONRO'S *Manual of Medicine* makes a second appearance and, although certain details in a very large book did not escape criticism, there is no doubt that we have in this work an excellent system of medicine both for the practitioner and the student. A tenth edition of Dr. T. H. GREEN'S *Introduction to Pathology and Morbid Anatomy* has been published under the editorship of Dr. BOSANQUET, and although no change has been made in the general plan of the work thorough revision has been entailed by the rapidity of pathological progress.

One of the most interesting books on surgery published during the year is the report on the Surgical Cases occurring in the South African War, a compilation edited by Surgeon-General W. F. STEVENSON, C.B., and containing contributions from Lieutenant-Colonel G. H. SYLVESTER, Lieutenant-Colonel S. HICKSON, Major MALLINS, and Major M P. HOLT, D.S.O., all members of the Army Medical Service. The report is worthy of close study not only by military surgeons but by all in civil practice, for it brings home to the civilian surgeon the extent to which the conditions met with in peace are modified as far as they obtain to hospital practice in war. Lieutenant-Colonel ROBERT CALDWELL'S *Military Hygiene* may well be read as a pendant to the report. It should become the *vade mecum* with the officers of the Royal Army Medical Corps and the Indian Medical Service, and is the most valuable treatise on the subject since the classic work of the late Professor Parke.

Two works on pharmacology and therapeutics may well find a permanent home in the libraries of medical men. One is Dr. WALTER DIXON'S *Manual of Therapeutics*, the object of which is to give the student a simple account of the science viewed from the modern standpoint, and the other is the colossal American compilation, the *National Standard Dispensatory*, edited by Dr. HOBART A. HARE and contributed to by many distinguished American professors of therapeutics, pharmacology, chemistry, and botany. The *Dispensatory* is a storehouse of modern pharmacological and pharmaceutical knowledge; it has been compiled with earnestness and care, and British practitioners may note that the pharmaceutical actions and uses of all the medicines included in our Pharmacopœia will be found thoroughly dealt with. Dr. DIXON'S work is of a totally different scope and is not, indeed, a text-book of materia medica at all but a compact review of the leading facts and theories of pharmacology treated in a modern manner. The study of pharmacology of recent years has been neglected by the medical profession, and Dr. DIXON'S book may do valuable service in changing this attitude of coldness.

Climate nowadays bulks largely in the mind of the

Essentials of Histology (Longmans, 9*s.* net).—BRODIE'S *Essentials of Experimental Physiology* (Longman's,, 6*s.* 6*d.*).—These three books should be read to supplement HALLIBURTON'S *Kirkes' Physiology.*—STARLING'S *Elements of Human Physiology* (J. & A. Churchill, 12*s.* 6*d.*) is in its fourth edition and is also an excellent text-book.

THIRD EXAMINATION.

Medicine.—OSLER'S *Principles and Practice of Medicine*, sixth edition, thoroughly revised (Sidney Appleton, 21*s.* net).—A clear, well-arranged, and very readable book, perfectly up to date.—TAYLOR'S *Manual of the Practice of Medicine.*—(J. & A. Churchill, 16*s.*) Either of these books will be sufficient.—CARTER'S *Elements of Practical Medicine* (H. K. Lewis, 10*s.* 6*d.*) will serve as a sound foundation, but does not contain enough for the Conjoint examination.

Applied Anatomy.—TREVES'S (assisted by ARTHUR KEITH, M.D.) *Surgical Anatomy*, new edition (Cassell, 9*s.*)—HOLDEN'S *Landmarks, Medical and Surgical* (J. & A. Churchill, 3*s.* 6*d.*) also thoroughly deserves the popularity it has so long enjoyed as a book on applied anatomy, while the supplementary volume on Surgical Anatomy in QUAIN'S *Anatomy* by THANE and GODLEE (Longmans, 6*s.* 6*d.*) is excellent.

Pathology.—GREEN'S *Pathology* (Renshaw, 17*s.*) is an excellent work. — LAZARUS BARLOW'S *General Pathology* (J. & A. Churchill, 21*s.*).—BOWLBY'S *Surgical Pathology* (J. & A. Churchill, 10*s.* 6*d.*).—CURTIS'S *Essentials of Bacteriology* (Longmans, 9*s.*).

Materia Medica.—MITCHELL BRUCE'S *Materia Medica* (Cassell, 7*s.* 6*d.*) or HALE WHITE'S *Materia Medica* (Churchill).

Forensic Medicine.—LUFF'S *Forensic Medicine* (Longmans, 24*s.*). — AUBREY HUSBAND'S *Forensic Medicine* (Simpkin, 10*s.* 6*d.*).—Both books fit the examination.

Public Health.—PARKES and KENWOOD'S *Hygiene*, second edition (Lewis, 12*s.*).—This book is practically the seventh edition of Dr. Louis Parkes's *Hygiene.*—WHITELEGGE and NEWMAN'S *Hygiene* (Cassell, 7*s.* 6*d.*).—HAMER'S *Manual of Hygiene* (J. & A. Churchill, 12*s.* 6*d.*).—*A Handbook of Hygiene* (C. Griffin and Co., Limited, 8*s.* 6*d.* net), by A. M. DAVIES, Lieutenant-Colonel, R.A.M.C.—Each of these books may be recommended for the examination.

Surgery.—ROSE and CARLESS'S *Manual of Surgery*, sixth edition (Baillière, Tindall, and Cox, 21*s.*).—This book contains all that is necessary for the examination and has been regularly kept up to date.—WALSHAM and SPENCER'S *Theory and Practice of Surgery* (J. & A. Churchill, 15*s.*) is now in its ninth edition and deserves its popularity.—TREVES'S *System of Surgery* (Cassell, 48*s*) and TILLMANN'S *Surgery* (Appleton, 63*s.* net) may be consulted as books of reference. The student should also read a work on operative surgery, and the best for this purpose is TREVES'S *Student's Handbook of Surgical Operations* (Cassell, 7*s.* 6*d.*)—ALLINGHAM'S *Operative Surgery* (Baillière, Tindall, and Cox) is also good.—Every student will find SPENCER'S *Outlines of Practical Surgery* (Baillière, Tindall, and Cox, 12*s.* 6*d.*) of great help to him.

Midwifery.—GALABIN'S *Midwifery* (J. & A. Churchill, 15*s.*) or DAKIN'S *Midwifery* (Longmans, 18*s.*) is most exactly fitted for this examination. In Gynæcology we recommend HERMAN'S *Diseases of Women* (Cassell, 25*s.*). HERMAN'S *Difficult Labour* (Cassell, 12*s.* 6*d.*) may also be read.

The student should also read HARE'S *Practical Diagnosis*, fifth edition (Kimpton, 21*s.* net), which explains the use of symptoms in the diagnosis of disease. This book will, of course, only appeal to those in the fifth year of the curriculum, but to them it will prove very useful and suggestive. He must also read a Text-book of Ophthalmic Surgery; SWANZY'S book (Lewis, 12*s.* 6*d.*) is suggested as containing all that he is required to know. He should also read a work on Dermatology, such as NORMAN WALKER'S *Introduction to Dermatology* (Wright, 7*s.* 6*d.*) or MALCOLM MORRIS'S *Diseases of the Skin* (Cassell, 10*s.* 6*d.* net).

This does not seem a very large library for an earnest student to read in a curriculum extending over five years, but if the books are read properly they will amply suffice. For they have to be thoroughly mastered and completely assimilated. It must be acknowledged that whatever care be devoted to the making of a selective list the result will not be always perfectly satisfactory for every student. There is no work on any subject which is suitable for all candidates and all examinations. When there are two books of equal standing it may be impossible to say which is the better of the two, and it will be seen that we have in several cases given the reader a choice of alternatives. The proper foundation for a student's knowledge must be laid in his lectures and his practical work, and in some rare cases lectures and attendance in wards and at out-patient departments may entirely obviate the necessity for any text-book. To practical work especially the student must pay attention, for the knowledge learnt by practice is much more easily retained than that learnt only from a book, but in nearly all cases a treatise needs to be read.

BOOKS RECOMMENDED FOR THE HIGHEST QUALIFICATIONS.

The list of books given above as necessary to be read before the student can make certain of obtaining the diplomas of the Conjoint Board will if absolutely mastered go very far to take him through any higher examination—especially if his practical work be good and if he have an orderly mind and a ready wit, so that he is at his best during his tests; but in certain directions the aspirant for the medical degrees of the University of London, the Fellowship of the Royal College of Surgeons of England, and the Membership of the Royal College of Physicians of London must read more advanced works. The degrees of other universities may also require from their candidates a larger range of reading, but in these it is chiefly for the final examination, the standard of which is (or is expected to be) higher than the standard of the pass examinations of the various corporations. In the case of the University of London the increased stringency in the tests is felt from the beginning, although the matriculation is not so hard as it used to be; while the first examination for the Fellowship of the Royal College of Surgeons of England is one of the hardest and most uncertain examinations known to us. In making the suggestions which follow we premise in the student a knowledge of the simpler works.

For the Preliminary Scientific Examination of the University of London RIDEAL'S *Practical Organic Chemistry* (Lewis, 2*s.* 6*d.*), TILDEN'S *Inorganic Chemistry* (J. & A. Churchill, 10*s.*), REMSEN'S *Organic Chemistry* (Macmillan and Co., Limited, 6*s.* 6*d.*), and BERNAYS' *Practical Chemistry* (J. & A. Churchill, 4*s.* 6*d.*) are recommended. DANIELL'S *Text-books of Physics* (Macmillan and Co., Limited, 21*s.*) should be supplemented by DESCHANEL'S well-known volumes, LOWSON'S *Botany* (Clive, 6*s.* 6*d.*), and WELLS and DAVIES'S *Zoology* (Clive, 6*s.* 6*d.*). MUDGE'S *Zoology* (Arnold and Co., 6*s.*) is a book which is intended exactly to fit the needs of this examination, while the course of botanical reading should include SCOTT'S *Structural Botany* (Adam and Charles Black, two volumes, 3s. 6d. each.). For the Intermediate Examination in Medicine of the University of London and for the first Fellowship of the Royal College of Surgeons of England MORRIS'S *Anatomy* (J. & A. Churchill, 30*s.* net) is, on the whole, the best text-book, but the student should also read Embryology by SCHÄFER and Splanchnology by SCHÄFER and SYMINGTON in QUAIN'S *Anatomy* (Longmans, 9*s.* and 16*s.* respectively) and revise his osteology from time to time by GRAY'S *Anatomy* (Longmans, 32*s.* net) and his practical work by CUNNINGHAM'S *Practical Anatomy*

SESSION 1906–1907.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. The registration of medical students shall be placed under the charge of the branch registrars. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years, and has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than 15 days before the date of registration. In addition to the universities and schools of medicine there are several scientific institutions in 17 English towns and in Dublin where medical study may be commenced. In London these institutions are the Birkbeck Institute, the East London Technical College, the Central Technical College, Westfield College, Battersea Polytechnic Institute (day classes), Bedford College, Royal Holloway College, and the Royal College of Science. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

The Preliminary Examination in General Education, required to be passed previously to registration as a medical student, shall be as follows.—

1. English language, including grammar and composition. 2. Latin, including grammar, translation from unprescribed Latin books, and translation of English passages into Latin. 3. Mathematics, comprising (a) arithmetic, (b) algebra, including easy quadratic equations, and (c) geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions. 4. One of the following subjects: (a) Greek, (b) a modern language.

In many cases the Council will not accept certificates of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of medicine have been passed at the same time.

A degree in Arts of any university of the United Kingdom or of the colonies or a certificate of having passed the final examination for a degree in Arts or Science of any university in the United Kingdom shall be considered a sufficient testimonial of proficiency.

The following is a list of Examining Bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical or dental student.

I.—UNIVERSITIES IN THE UNITED KINGDOM.

University of Oxford.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Responsions. Moderations.

University of Cambridge.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Previous Examination. General Examination.

University of Durham.—Matriculation Examination for Science, Letters, and Music. Senior Local Examinations.

University of London.—Matriculation Examination.

Victoria University of Manchester.—Matriculation Examination.

University of Birmingham.—Matriculation Examination.

University of Liverpool.—Matriculation Examination.

University of Leeds.—Matriculation Examination.

University of Wales.—Matriculation Examination.

University of Edinburgh.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery.

University of Aberdeen.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery.

University of Glasgow.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery.

University of St. Andrews.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery. Final Examination for the diploma of L.L.A.

University of Dublin.—Public Entrance Examination. Examination for the first, second, third, or fourth year in Arts.

Royal University of Ireland.—Matriculation Examination.

Oxford and Cambridge Schools Examination Board.—Lower certificate (to fulfil the Council's requirements). Higher certificate (to include the required subjects). Leaving certificate (the subjects to be passed at one time).

II.—MEDICAL LICENSING BODIES.

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary Examination.

III.—EDUCATIONAL BODIES OTHER THAN UNIVERSITIES.

College of Preceptors.—Examination for a First Class Certificate; Preliminary Examination for Medical Students.

Intermediate Education Board of Ireland.—Middle Grade Examination; Senior Grade Examination.

Educational Institute of Scotland.—Preliminary Medical Examination.

Scottish Education Department.—Leaving Certificates in Lower and Higher Grades and in Honours.

Central Welsh Board.—Senior Certificate Examination.

IV.—INDIAN, COLONIAL, AND FOREIGN UNIVERSITIES AND COLLEGES.

Every Certificate from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at one time; copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classical Oriental Language may be accepted instead of an Examination in Latin. The German Abiturienten-Examen of the Gymnasia and Real-gymnasia and the examinations entitling to the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences are recognised by the General Medical Council.

Professional Education.—The course of professional study after registration shall occupy at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

H. E. Allen, LL.B., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 48, George-square, Edinburgh.—Richard J. E. Roe, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

POWERS AND DUTIES OF THE GENERAL MEDICAL COUNCIL.

As there is apparently, even among members of the medical profession, a great amount of ignorance as to the powers and duties of the General Medical Council, we think it well to lay clearly before our readers what the General Medical Council is and also what it is not.

Many of the false ideas on the subject are due to the use of the shortened title, "General Medical Council." The full title is, "General Council of Medical Education and Registration of the United Kingdom." This title is in accordance with the Medical Act of 1858, by which the General Medical Council was established to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. Registrars were to be appointed by the General Council and by the Branch Councils to keep registers of qualified persons. Registrars were bound by Section XIV. of the Act to keep their registers correctly, a duty which, mainly owing to the apathy of thoughtful physician, for the world is now so opened up that to advise patients to go abroad is no longer in many instances an amiable method of telling them that nothing more can be done. A large number of our population, if the worst comes to the worst, can find sufficient money to change latitude and longitude in search of health. Dr. William R. Huggard, Consul at Davos, and a well-known authority on climatology and balneological treatment of disease, has produced a handbook of *Climatic Treatment* which gives in a readable form information which the general practitioner nowadays is expected to have at his fingers-ends. Dr. Huggard is critical in his consideration of climate, and the rigid analysis to which he subjects health resorts and watering-places makes his book of real practical value.

No subject concerns the politician, the humanitarian, or the sanitarian more deeply than the grave rate of infantile mortality that prevails in so many localities. Speaking generally, the care of the infant is recognised as the most effective way of combating conditions of race deterioration, so that the vigorous discussion which has recently taken place about our national physique has drawn the attention of the public constantly to the conditions of child-life. On the subject of infantile mortality Dr. George Newman, medical officer of health of Finsbury, has written an authoritative volume, so far the only modern text-book, we believe, of any pretension to scientific accuracy that is available for the English reader on the subject. The mass of information contained within the comparatively brief space of 360 pages is somewhat surprising, but the author has his interesting subject at his fingers' ends and has made good uses of his sources of information. Of many causes of the grave mortality among infants which our statisticians have to report to us maternal ignorance is not the least influential, and as this is now recognised by all whose work lies among the poorer classes it is not surprising that many books dealing with the upbringing of children are published annually. In this place we need only refer to one little book entitled *The Care and Management of Delicate Children*, by Dr. Percy Lewis, which, without being particularly original, summarises in a very sensible and temperate manner the best theories of treatment. Dr. Lewis's book is intended, no doubt, as much for the public as for medical men, but many practitioners will benefit by the information it contains. New editions of Dr. Henry Ashby's *Diseases of Children* and Dr. L. Emmett Holt's *Diseases of Infancy and Childhood* have appeared during the year.

The second volume of Mr. J. H. Parsons's *Pathology of the Eye* has been published and maintains the high standard reached in the first volume. A very large quantity of original matter is presented to the reader, as well as convenient summaries of the observations of other authors. Profuse illustration, clear style, and complete mastery of the subject conduce to the production of an excellent treatise.

Two works on physiology have appeared during the year which are worth bringing to the attention of our readers. Dr. W. H. Howell's *Text-book for Medical Students and Physicians* we have recommended in a recent review as one of the best books on physiology that has lately come under our hands. The subjects are concisely treated, a small but sufficient number of references is given, and the application of physiology to the many pathological problems of modern medicine is clearly indicated. The second work, *Recent Advances in Physiology and Bio-Chemistry*, is edited by Dr. Leonard Hill and has been contributed to by some of our best-known physiological thinkers. The work will prove of value to students in higher examinations as well as to medical men whose lot it is to have opportunity for carrying on research work.

A right understanding of the relationship existing between the medical man and his patient is highly important to the medical man, and if the public considered this relationship more accurately many professional grievances would disappear. That the lay press does not always rightly appreciate the position of the medical profession is shown by the not infrequent occasions on which statements which are unfair to the practitioner are published, and the public, taking their cue from this biased information, in turn do scant justice to our science. The public is not well informed as to the difficulties of the medical man. *Medicine and the Public*, by Dr. S. Squire Sprigge, a book the greater part of which appeared in the columns of The Lancet, has been written with the object of making clear to the lay mind the disabilities under which much medical practice is carried on. In it members of the medical profession and medical students will find discussed in very plain and simple terms most of the professional problems of the day, while references to The Lancet will provide an easy opportunity of obtaining fuller information upon any particular point.

MEDICAL TEACHERS.

Mr. R. O. B. Kerin, B.A. London, first in First Class Honours in Classics, assisted by a staff of B.A. and B.Sc. Honour Graduates, prepares candidates in class and by private tuition for Medical Preliminaries, London Matriculation, Preliminary Scientific Inter. Science, First Conjoint, First M.B. Lond., Oxon., and Camb., &c. Hospital Scholarships. Biological, Chemical, and Physical Laboratories.—Carlyon College, 55 and 56, Chancery-lane, W.C.

The University Examination Postal Institution prepares candidates either through the post or orally for all Medical Examinations. Ten of the regular staff hold the M.D. or M.S. degree, of whom seven are gold medallists. Laboratory, Microscopic, and Museum work if desired. The Manager is Mr. E. S. Weymouth, M.A., 27, Southampton-street, Strand, London, W.C.

Special preparations, in class, privately, and by correspondence, for the Triple Qualification, Edinburgh. Also for Fellowship Examinations of the Royal College of Surgeons, Edinburgh, and M.D. Brussels. Resident pupils received.—Address, Class Rooms, 7, Chambers-street, Edinburgh.

Mr. D. W. Patterson, M.B., B.S. Durh. (First Honours), Luke Armstrong and Charlton Scholar, Gibson Prizeman, Coaches in all the professional subjects of the M.D. Durh. exam.—Dr. Patterson, 26, Ellison-place, Newcastle-on-Tyne.

Coaching by experienced Honours Graduates (Medicine, Surgery, Science) for M.D. (Lond. and Cambridge), M.D. Durham (15 years' standing), M.D. Brux., Primary Fellowship, D.P.H., the Services, 1st, 2nd, and Final Conjoint. Tuition in class, privately or by post, in Medicine, Surgery, Anatomy, Physiology, Materia Medica, Chemistry, Biology, &c. Laboratory. Special Correspondence Courses for M.D. Lond., M.D. Durh., F.R.C.S., D.P.H., &c.—E. Gooch, B.Sc., 115, Gower-street, W.C.

Coaching in Anatomy and Physiology with practical work and instruction in Chemistry, Physics, Materia Medica, and Biology is given by B.Sc., 9, Heathcote-street, Gray's Inn-road, London.

D.P.H. Classes.—These classes qualify for the various Examining Boards. Information can be obtained from Mr. G. H. Gemmell, F.I.C., F.C.S., Chemical Laboratory, School of Medicine, 4, Lindsay-place, Edinburgh.

Correspondence Classes for the Fellowship of the Royal College of Surgeons, Edinburgh.—Particulars from Dr. Knight, 7, Chambers-street, Edinburgh.

Indian Medical Service and R.A.M.C. Classes are held at the Passmore Edwards' Settlement, Tavistock-place, Russell-square, London, W.C.

Mr. I. Beckton, 37, Store-street, Bedford-square, W.C., prepares students for Matriculation, Preliminary Medical and Law, and other examinations.

The London College of Chemistry, Pharmacy, and Botany, 323, Clapham-road, London, S.W.—Principal, Henry Wootton, B.Sc. Lond. This College is established for the purpose of providing thorough and practical instruction in all branches of science, especially for students preparing for Pharmaceutical, Medical, and University Examinations. There are laboratories and class rooms, and special classes are held daily in preparation for the Medical and Pharmaceutical Preliminary Examination of the College of Preceptors, fee 4 guineas per term of three months commencing Sept. 25th.

Westminster College of Chemistry and Pharmacy, Ltd., Trinity-square, Borough, S.E.—Principal, G. S. V. Wills, F.L.S.; Secretary, J. E. Walden. Special instruction given to medical and dental students in chemistry, physics, and pharmacy. Fees and time by arrangement. Ladies are prepared for the Dispenser's Examination of the Apothecaries' Hall at the Apothecaries' College for Ladies, 112, St. George's-road, Southwark, S.E., which has been recently established by the above College.

Instructors in Elocution, &c.

Mr. William Van Praagh, the public introducer of the Pure Oral System of teaching Deaf Mutes, has made the subject of Lip-reading and the cure of all Defects of Speech, both acquired and congenital, his special study. Papers on the various subjects can be had at 11, Fitzroy-square, W.

Mrs. Emil Behnke gives instruction in Voice Training and treat- Stammering and other Defects of Speech at 18, Earl's-court square, S.W.

examination every year by most of the Colleges. Notices of vacancy, &c., are published in the *University Gazette*, and all particulars may be obtained by application to the Science Tutors of the several Colleges. One Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. The examination is partly scientific, partly medical. Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years standing for an original research in some Biological subject, including Physiology or Pathology.

The Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of Pathological Research.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1902, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University (all of which are published by the Clarendon Press); from the Regius Professor of Medicine; and from the Professors in the several departments of medical science.

The Lecturers for the various subjects are as follows:—Medicine: W. Osler, D.M., Regius Professor. Professor of Human Anatomy: A. Thomson, M.A. Waynflete Professor of Physiology: F. Gotch, M.A., D.Sc. University Lecturer on Physiology: J. S. Haldane, M.A. Histology: G. Mann, D.M. Edin. Physiological Chemistry: Walter Ramsden, D.M. Practical Physiology: H. M. Vernon, D.M. Pathological Histology and Practical Bacteriology: The Professor of Pathology, J. Ritchie, D.M. Edin. Lichfield Lecturer in Clinical Medicine: W. T. Brooks, M.A. Lichfield Lecturer in Clinical Surgery: H. Anglin Whitelocke, F.R.C.S. Organic Chemistry in Relation to Medicine, &c., followed by Practical Work: W. W. Fisher, M.A. (Aldrichian Demonstrator), and J. E. Marsh, M.A. Lecturer in Materia Medica and Pharmacology: W. J. Smith Jerome, B.M. Lond. Linacre Professor of Comparative Anatomy: W. F. R. Weldon, M.A., D.Sc. Lees Reader in Anatomy: J. B. Thompson, M.A. Elementary Animal Morphology (Practical): The Aldrichian Demonstrator, E. Goodrich, M.A., and assistants. Sherardian Professor of Botany: S. H. Vines, M.A. Waynflete Professor of Chemistry: W. Odling, M.A. Lees Reader in Chemistry: G. Brereton Baker, M.A. Laboratory Instruction: W. W. Fisher, M.A., J. Watts, M.A., and J. E. Marsh, M.A. Wykeham Professor of Physics: J. S. E. Townsend, M.A. Professor of Experimental Philosophy: R. B. Clifton, M.A. Instruction in Practical Physics: R. B. Clifton, M.A., J. Walker, M.A. Elementary Heat and Light: Lees Reader in Physics, R. E. Baynes, M.A. Elementary Mechanics: F. J. Jervis-Smith, M.A.

In addition to the University Lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the B.A. degree.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., which may, and should if possible, be done before coming into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A. or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M.B. examinations.

For the degree of *Bachelor of Medicine (M.B.)* five years of medical study are required. This time may be spent in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed, say, the examination for the Natural Sciences Tripos and the first and second, and the first part of the third, examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection is abundant, and the laboratories for Pathology, Bacteriology, and Pharmacology are well equipped. Addenbrooke's Hospital provides for the necessary clinical training.

There are three examinations for M.B. The *first* includes Chemistry and other branches of Physics and Elementary Biology. These parts may be taken together or separately. The *second* includes Human Anatomy and Physiology. The *third* is divided into two parts—viz., (1) Pharmacology and General Pathology; (2) Principles and Practice of Surgery, Midwifery and Diseases Peculiar to Women, Principles and Practice of Physic. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself on some subject approved by the Regius Professor of Physic.

As Operative and Clinical Surgery now form parts of the third M.B. examination candidates who have passed both parts of that examination are admitted to the registrable degree of *Bachelor of Surgery (B.C.)* without separate examination and without keeping an Act.

The degree of *Doctor of Medicine (M.D.)* may be taken three years after that of M.B. or four years after that of M.A. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

For the degree of *Master of Surgery (M.C.)* the candidate must have passed all the examinations for B.C., or if he is an M.A. have obtained some other registrable qualification in surgery. He is required either (1) to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery, and to write an extempore essay on a Surgical Subject; or (2) to submit to the Medical Board original contributions to the advancement of the Science or Art of Surgery. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.C. Before submitting original contributions he must have been qualified at least three years.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, Cambridge.

UNIVERSITY OF LONDON.

The Matriculation Examination.—The examinations take place three times in each year—namely, on Sept. 15th (if that day be a Monday, or if not, on the Monday next preceding the 15th), on the second Monday in January, and on the second Monday in June (or July, as may be hereafter determined). The examinations in January and June (or July), but not that in September, may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies. Every candidate must, on or before August 24th for the September examination, on or before Nov. 25th for the January examination, and on or before April 25th for the June (or July) examination, apply by postcard to the Principal for a form of entry, of which the first in order must be returned 14 days before the commencement of the September examination, the second on or before Dec. 1st, and the third on or before May 1st, accompanied in the same cover by a certificate showing that the candidate has completed his sixteenth year, and by his fee for the examination. A certificate from the Registrar-General in London or from the superintendent members of the medical profession, has not been adequately performed.

It will thus be seen that the General Medical Council is primarily a body of gentlemen charged with looking after the education and registration of medical practitioners. The sole penalty it can inflict is to strike a man's name off the Medical Register. It is as well here to put down the advantages, such as they are, of being duly registered. A duly registered practitioner may sue in the courts of law for the recovery of charges for medical attendance or advice, or surgical attendance or advice, or for the supply of medicine, or for the performance of any operation—provided that he is not debarred from suing by being a Fellow or a Member of any corporation which objects to its Fellows or Members so suing. He may be exempted, if he so desire, from serving on juries, from serving sundry corporate and parochial offices, and from serving in the Militia. Only a registered practitioner can hold appointments in the navy, army, and sundry Poor-law and other institutions. Only a registered person can sign a valid medical certificate. Removal of the name from the Register debars a man from all the above-mentioned privileges.

The General Medical Council is in no way a medical protection society or a medical defence union. It is not a professional union or a guild charged with looking after the interests of the medical profession after the manner of the old trades guilds, except in so far as it is concerned with the education of medical students. It has no powers over any member of the medical profession except to remove the name of any offending member from the roll of the profession or Medical Register. It cannot take away any degree, or diploma, or licence, and even if a practitioner is struck off the Medical Register there is nothing in the existing state of the law to prevent such practitioner continuing to practise, provided that he does not use any name or title implying that he is registered. Practitioners may be removed from the Medical Register (1) if convicted of felony or misdemeanour in England, or in Ireland, or in Scotland of any crime or offence, and (2) on being adjudged by the General Medical Council to have been guilty of "infamous conduct in a professional respect."

The General Medical Council is, we repeat, primarily a body charged with looking after medical education; it is but little concerned with medical politics and, as a matter of fact, the time of the Council is almost entirely taken up with considering educational and registration matters, the latter including the penal cases of removal from the Register. The Council at present consists of 33 members, of whom, as will be seen by the annexed list, all but 10 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and five others are elected by the members of the medical profession as Direct Representatives.

President of the General Council.—Dr. Donald MacAlister. Members of the General Council.—Dr. Norman Moore, chosen by the Royal College of Physicians of London; Mr. Henry Morris, Royal College of Surgeons of England; Sir Hugh Reeve Beevor, Bart., Apothecaries' Society of London; Mr. Arthur Thomson, M.B., University of Oxford; Dr. Donald MacAlister, University of Cambridge; Sir George Hare Philipson, University of Durham; Dr. Philip Henry Pye-Smith, University of London; Mr. Alfred Harry Young, M.B., Victoria University of Manchester; Dr. Robert Saundby, University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Alfred George Barrs, University of Leeds; and Dr. William Tusting Cocking, University of Sheffield. Sir John Batty Tuke, M.P., chosen by the Royal College of Physicians of Edinburgh; Dr. James William Beeman Hodsdon, Royal College of Surgeons of Edinburgh; Dr. John Lindsay Steven, Faculty of Physicians and Surgeons of Glasgow; Sir Thomas Richard Fraser, M.D., University of Edinburgh; Sir Thomas McCall Anderson, University of Glasgow; Dr. David White Finlay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore chosen by the Royal College of Physicians of Ireland; Sir Thomas Myles, Royal College of Surgeons in Ireland; Dr. Francis George Adye-Curran, Apothecaries' Hall of Ireland; Sir Charles Ball, University of Dublin; and Sir Christopher John Nixon, Bart., Royal University of Ireland. Nominated by His Majesty, with the advice of his Privy Council: Mr. Charles Sissmore Tomes, Mr. William Henry Power, C.B., Sir John Williams, Bart., K.C.V.O., Dr. David Caldwell McVail, and Dr. James Little. Elected as Direct Representatives: Mr. George Brown, Sir Victor Alexander Haden Horsley, Mr. George Jackson, Dr. William Bruce, and Dr. Leonard Kidd. Treasurers of the General Council: Dr. Philip Henry Pye-Smith and Mr. Charles Sissmore Tomes.

REGULATIONS
OF THE
MEDICAL EXAMINING BODIES IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M. and D.M.*, and two degrees in Surgery, *B.Ch. and M.Ch.*

Graduates in Arts (B.A. or M.A.) are alone eligible for these degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. In order to obtain the degrees of B.M. and B.Ch. the following examinations must be passed:—1. Preliminary subjects: Mechanics and Physics, Chemistry, Animal Morphology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology, unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy and Materia Medica with Pharmacy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, Physics, and Chemistry, December and June; Animal Morphology, December and March; Botany, March and June; Professional (First and Second B.M.), June and December.

The First Examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first but Pathology and Hygiene may be taken before or with the remaining subjects. Before admission to the Second Examination candidates must present Certificates of attendance or a course of laboratory instruction in Practical Pathology and Bacteriology and of having acted as post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also he must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination. Also in respect of the First Examination candidates must present certificates showing that they have dissected the whole body once and have attended courses of laboratory instruction in Practical Histology and Practical Physiology.

The degree of D.M. is granted to Bachelors of Medicine of the University provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The Regius Professor may direct the dissertation to be read in public. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed the M.Ch. examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second B.M. Examination.

Scholarships, &c.—Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive in October, 1904. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination. Every candidate must produce certificates of having passed the intermediate examination and of having subsequently attended courses of instruction in (1) Principles and Practice of Medicine; (2) Clinical Methods and Physical Diagnosis; (3) Insanity; (4) Therapeutics; (5) Vaccination; (6) Principles and Practice of Surgery; (7) Operative Surgery, Surgical Anatomy, Practical Surgery, and the Administration of Anæsthetics; (8) Diseases of the Eye, Ear, and Throat: (9) Midwifery and Diseases of Women; (10) Practical Midwifery, the conduct of at least 20 Labours, and practice as a Clinical clerk in Gynæcological work; (11) Pathology and Bacteriology; (12) work of the Post-mortem room; (13) Forensic Medicine; and (14) Hygiene. He must also have attended the Medical and Surgical practice of a recognised hospital for two years and a fever hospital for two months. For internal students the above form the subjects of the fourth and fifth years of study as prescribed by the University. Candidates as external students in medicine must have been engaged in professional study during five years subsequent to matriculation and four years subsequent to passing the Preliminary Scientific Examination Part I. at one or more of the schools recognised by the University for the purpose. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The fee is £10 for each entry to the whole examination and £5 for examination or re-examination in either group. There will be no separate examination held for Honours but the list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates must have taken the degrees of M.B., B.S. not less than two years previously but for those who have taken the M.B., B.S. degrees with Honours or have done certain original work this period of delay may be reduced to one year. They may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Certain conditions have to be fulfilled in each case, varying according to the nature of the branch in question. Any candidate for the degree of M.D. may transmit to the Registrar, not less than two months before the commencement of the examination, a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from the written examination. The fee is £20.

Master in Surgery.—The examination for the degree of Master in Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July. Candidates must produce certificates of having taken the degrees of M.B. and B.S. not less than two years previously and of having subsequently held for at least six months a resident or non-resident Surgical hospital appointment. The examination is conducted by means of printed papers and *vivâ-voce* interrogation, and the subjects are Surgery, Surgical Pathology and Anatomy, a Clinical examination, and operations on the dead body. Any candidate for the degree of M.S. may transmit to the Registrar, not later than two months before the commencement of the examination, a thesis or published work having definite relation to Surgery, and if the thesis be approved by the examiners the candidate may be exempted from the written examination in Surgery. The fee is £20.

UNIVERSITY OF DURHAM.

One Diploma and six degrees are conferred—viz., the Diploma in Public Health and the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene. These degrees are open both to Men and Women.

For the degree of *Bachelor in Medicine* (*M.B.*) there are four professional examinations. The subjects of the First Examination are—Elementary Anatomy and Elementary Biology, Chemistry, and Physics. The subjects of the Second Examination are—Anatomy, Physiology, Materia Medica, Therapeutics, Pharmacology, Pharmacy. The subjects for the Third Examination are—Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Diseases of Women and Children.

N.B.—It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery* (*B.S.*) every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham and must have attended one course of lectures on Operative Surgery and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery* (*M.S.*) candidates must not be less than 24 years of age and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in one of these subjects at the Preliminary Examination in Arts for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The subjects of examination are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

For the degree of *Doctor in Medicine* (*M.D.*) candidates must be not less than 24 years of age and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in one of these subjects at the Preliminary Examination in Arts for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Medicine in attendance on the practice of a recognised hospital, or in the military or naval services, or in medical and surgical practice. Each candidate must present an essay prepared entirely by himself, which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved of by the Professor of Medicine and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subject of the essay.

Doctor of Medicine (*M.D.*) (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession, and if they have not passed an examination in Arts previously to the Professional Examination in virtue of which they have been placed on the Register, they shall be required to pass in Classics and Mathematics. Candidates who have passed an examination in Arts previously to being placed on the Register are required to pass an examination in Latin. They will be examined in the Principles and Practice of Medicine, including Psychological Medicine, Hygiene, and Therapeutics, the Principles and Practice of Surgery, Midwifery.

registrar of the district, or a certified copy of the baptismal register, or a declaration of the candidate's age, made before a magistrate by his parent or guardian, or by the candidate if of full age, will be accepted. As candidates cannot be admitted after the list is closed any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Principal, stating the exact date of his application and the place where it was posted. Every candidate must pay a fee of £2. If he withdraws his name before the last day of entry it shall be returned to him. If he fails to present himself he shall be allowed to enter for a subsequent Matriculation within eight months on payment of £1. If he retires after the commencement of the examination or fails to pass it the full fee of £2 shall be payable on every re-entry. Candidates must show a competent knowledge of each of the following five subjects, according to the details specified: 1. English—Composition, Précis-writing, salient facts in English History and Geography. 2. Elementary Mathematics—Arithmetic, Algebra (including quadratic equations and graphs of simple functions), and the subjects of Euclid (Books I. to IV.). 3. Latin, or Elementary Mechanics, or Elementary Physics (Heat, Light, and Sound), or Elementary Chemistry, or Elementary Botany. 4 and 5. Two of the following subjects, neither of which has been taken under Section 3 (if Latin be not taken one of the other subjects must be another language from the list): Latin, Greek, French, German, Ancient History, Modern History, Logic, Physical and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced), Elementary Mechanics, Elementary Chemistry, Elementary Physics (Heat, Light, and Sound), Elementary Physics (Electricity and Magnetism), and Botany. Additional subjects, of which, however, candidates must give notice two months previous to the examination, are: Arabic, Sanskrit, Spanish, Portuguese, Italian, Hebrew, and Zoology. A pass certificate signed by the Principal is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate. Students of the University may be either internal or external. Internal students are those who have matriculated at the University and are studying in a school or schools or under one or more of the teachers of the University. The medical schools in question are those connected with University College Hospital, King's College Hospital, St. Bartholomew's Hospital, the London Hospital, Guy's Hospital, St. Thomas's Hospital, St. George's Hospital, the Middlesex Hospital, St. Mary's Hospital, Charing Cross Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. For external students see under M.B., B.S. Examination.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Principal of the University, who will then make all necessary arrangements. Besides the University fee, a fee usually varying from £1 to £3 is charged by the local authorities and must be paid at the local centre immediately before the commencement of the several examinations.

Preliminary Scientific Examination.—The Preliminary Scientific Examination, Part I. (Inorganic Chemistry, Physics, and Biology) will take place twice in each year, commencing on the third Monday in January and on the second Monday in July. It must be passed by internal students not less than one academic year after matriculation and by external students not less than nine months after matriculation. Every candidate must apply (internal students to the academic registrar and external students to the external registrar) for a Form of Entry on or before May 24th or Dec. 5th, which must be returned, accompanied by the proper fee, not later than June 1st for the July examination or Dec. 12th for the January examination. The fee is £5 for each entry to the whole examination, provided that all the subjects are taken at one time. When less than the whole examination is taken at one time it is £2 for each subject. The examination will include papers, practical work, and oral questions on Inorganic Chemistry, Physics, Botany, and Zoology. Candidates must present themselves either (1) in Inorganic Chemistry, Physics, and Biology; or (2) in Inorganic Chemistry and Physics; or (3) in Biology. If they fail in any one subject they may present themselves for re-examination in that subject alone, provided that if they fail in both inorganic chemistry and physics they must present themselves for re-examination in these two subjects taken together. Part II. of the Preliminary Scientific Examination will take place twice in each year, commencing on the Thursdays following the third Monday in January and the second Monday in July. No candidate will be admitted to this examination within six months of having passed Part I. Every candidate must apply (internal students to the academic registrar and external students to the external registrar) for a form of entry on or before May 24th or Dec. 5th, which must be returned not later than June 1st for the July examination or Dec. 12th for the January examination. No fee will be charged for a first entry, but £2 will be charged for each subsequent entry. The examination will include a paper, practical work, and oral questions in Organic Chemistry.

Bachelor of Medicine and Surgery.—Every external candidate for the degree of Bachelor of Medicine and Surgery will be required—1. To have passed the Matriculation examination in this University not less than five years previously. 2. To have passed the Preliminary Scientific examination Part I. (Inorganic Chemistry, Physics, and Biology) not less than nine months after Matriculation, and the Preliminary Scientific examination Part II. (Organic Chemistry) not less than six months after Part I. 3. To have been engaged in his professional studies during five years subsequently to Matriculation and four years subsequently to passing Part I. of the Preliminary Scientific examination at one or more of the medical institutions or schools recognised by this University, one year at least of the four being spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine. In order to be admitted to the Bachelor's degrees internal students are required—1. To have attended prescribed courses of study in one or more schools of the University for five years after registration as internal students. 2. To have passed Part I. of the Preliminary Scientific Examination not less than one year after Matriculation, and Part II. of the same examination not less than six months after Part I. 3. To have passed two examinations in Medicine.

Intermediate Examination.—The Intermediate examination in Medicine takes place twice in each year, commencing on the third Monday in January and on the first Monday in July. The subjects of the examination are Anatomy, Physiology and Histology, and Pharmacology, including Materia Medica. No candidate shall be admitted to this examination unless he have passed Part I. of the Preliminary Scientific examination at least two years previously and Part II. at least one year previously. Internal students must have completed the second and third years' course of study prescribed for them by the University and external students must produce certificates of having subsequently to having passed Part I. of the Preliminary Scientific examination been a student during two years at one or more of the medical institutions or schools recognised by this University and of having attended (1) a course of not less than 100 lectures on Anatomy; (2) a course of Dissections for not less than 12 months; (3) a course of not less than 60 lectures on Physiology; (4) courses of Experimental Physiology, Histology, and Physiological Chemistry for not less than three months each; (5) lectures and demonstrations on Pharmacology, Pharmacy, and Materia Medica for not less than three months; and (6) Practical Pharmacy for not less than two months. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the Registrar at least four weeks before the commencement of the examination. Fee for this examination £10.

M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the last Monday in October and on the first Monday in May. No candidate will be admitted to this examination within two academic years from the date of passing the Intermediate examination. The M.B., B.S. examination under the regulations now described was held for the first time addition he will be required to pass a general examination in Principles and Practice of Medicine. It will be in the power of the Board of Examiners to exempt a candidate whose thesis is of exceptional merit from any part of these examinations.

A thesis may be presented in any of the following departments of study: (*a*) Anatomy, including Comparative Anatomy, (*b*) Physiology, (*c*) Human or Comparative Pathology, (*d*) Bacteriology, (*e*) Pharmacology, (*f*) Therapeutics, (*g*) Medicine, (*h*) Mental Diseases, (*i*) Preventive Medicine or Public Health, (*j*) Toxicology, (*k*) Legal Medicine, (*l*) Midwifery.

Candidates for the degree of Ch.M. are required to comply with the following regulations:—At the end of one year from the date of having passed the final M.B., Ch.B. Examination candidates will be eligible to present themselves for the higher degree of Master of Surgery. Candidates for this degree will be required to comply with the following regulations: 1. Every candidate shall present a thesis, embodying observations in some subject embraced in one of the departments of the medical curriculum enumerated below; in addition the candidates will be required to pass a general examination in Principles and Practice of Surgery and to perform operations on the cadaver. 2. It will be in the power of the board of examiners to exempt a candidate whose thesis is of exceptional merit from any part of these examinations. 3. The candidate may be examined in that department of the medical curriculum from which the subject of his thesis is chosen and the examiners may require to see the notes of original observations on which the thesis is based, (*a*) Surgery, (*b*) Pathology, (*c*) Bacteriology, (*d*) Gynæcology, (*e*) Ophthalmology.

Degree in Public Health.—For the regulations for this degree and for the diploma in the same subject see p. 616.

Fees.—Matriculation, £2; First Examination, £2; Second Examination, £2; Third Examination, £2; Fourth Examination, £2; Final Examination, £2; Admission Fee to degrees of M.B., Ch.B., £6: M.D. or Ch.M., £2; Admission Fee to degree of M.D. or Ch.M., £8.

UNIVERSITY OF LIVERPOOL.

The student must pass either (1) the University Matriculation Examination, or (2) the Final Examination for Graduation in Arts of any university in Great Britain and Ireland, or (3) the Matriculation Examination of the University of London, or (4) the Higher Certificate Examination of Oxford and Cambridge Joint Board, or (5) the Senior Local Examination of Oxford or Cambridge, with honours, or (6) some other examination of equal standard accepted by the Joint Matriculation Board. The course of professional study, subsequent to passing the Matriculation Examination and having been registered as a medical student, extends over five years. The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 21 years on the day of graduation. At least two of the five years of medical study must have been passed in the university, and one year at least must have been passed in the university subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the university. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry, Inorganic and Organic; (2) Biology (Zoology and Botany); and (3) Physics The examination is divided into two parts—namely (1) chemistry and physics, and (2) biology; and candidates may pass in these parts separately. The subjects of the Second Examination are (*a*) Anatomy and Physiology (including Physiological Chemistry and Histology), and (*b*) Materia Medica and Pharmacy. Candidates may pass in *a* or *b* separately. The subjects for the Final Examination are (1) Pharmacology and Therapeutics; (2) General Pathology and Morbid Anatomy; (3) Forensic Medicine and Toxicology, and Public Health; (4) Obstetrics and Diseases of Women; (5) Surgery, Systematic, Clinical, and Practical; and (6) Medicine, Systematic, and Clinical, including Mental Diseases and Diseases of Children. Candidates may either present themselves in all the six subjects of examination on the same occasion, or may pass the examination in two parts, the first part consisting of two or three of subjects (1), (2), and (3); the second part of the remaining subjects. Candidates for the first part of the examination must have completed the fourth winter of medical study in accordance with the regulations of the university.

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degrees of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since he passed the examinations for those degrees. Candidates for the degree of Doctor of Medicine are required to furnish three copies, preferably printed or typewritten, of the dissertation or published work which they desire to submit to the university. The subjects of examination for the degree of Master of Surgery are (1) Surgical Anatomy, (2) Surgery, (3) Operative Surgery, (4) Clinical Surgery, (5) Ophthalmology, and (6) Pathology and Bacteriology.

UNIVERSITY OF LEEDS.

Candidates presenting themselves for Matriculation in the Faculty of Medicine must pass an examination in English (Language or Literature) and English History, Mathematics and Latin, and in two of eight optional subjects. Exemption from the matriculation examination is granted to graduates of any university of the United Kingdom provided Latin has formed part of one of the degree examinations.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and that they have attended courses of instruction approved by the University extending over not less than five years, two of such years, at least, having been passed in the University subsequently to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry: Part II., Biology. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy Candidates will be allowed to pass the two parts separately.

The Final Examination.—The subjects of the Final Examination are: (1) Pharmacology and Therapeutics; (2) Pathology and Bacteriology; (3) Forensic Medicine and Toxicology and Public Health; (4) Obstetrics and Gynæcology; (5) Surgery: Systematic, Clinical and Practical; and (6) Medicine: Systematic and Clinical, including Mental Diseases and Diseases of Children.

Candidates may either present themselves in all the six subjects of examination on the same occasion or may pass the examination in two parts, the first part consisting of two or three of the subjects (1), (2), and (3); the second part consisting of the remaining subjects. Candidates who fail to satisfy the examiners in the first part must either present themselves again in the subjects as selected, or in all the three subjects of the first part, or in all the six subjects of examination.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, to pass an examination. The dissertation, of which the subject must previously have received the approval of the Board of the Faculty of Medicine, must embody the results of personal observation or original research, either in some department of medicine or of some science directly related to medicine, provided and Diseases of Women and Children, *Pathology* (Medical and Surgical), Anatomy (Medical and Surgical), Medical Jurisprudence, and Toxicology. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees must give at least 28 days' notice to Professor Howden, Secretary, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays six weeks before the date of the examination.

THE VICTORIA UNIVERSITY OF MANCHESTER.

Matriculation, which consists in signing the University Register, must precede entry upon any course of study. Those only can matriculate who are registered students of the University.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required to pass an examination called the Matriculation Examination (Faculty of Medicine), or to have passed such other examination as may be recognised by the University for this purpose.[1]

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the First M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations: the First Examination, the Second Examination, the Third Examination, and the Final Examination.

The First Examination.—The subjects of examination are as follows:—(1) Chemistry; (2) Physics; (3) Biology; (4) Materia Medica. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into three parts: Part 1, Physics and Chemistry; Part 2, Biology; Part 3, Materia Medica; and the candidates may pass in these parts separately under certain conditions.

The Second Examination.—The subjects of examination are as follows:—(1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology. Candidates may pass in (1) and (2) separately under certain conditions.

The Third Examination.—(1) Pathology; (2) Pharmacology and Therapeutics; (3) Hygiene. These subjects may be taken separately under certain conditions.

The Final Examination—The subjects of examination are as follows:—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Midwifery and Gynæcology (including Practical Gynæcology); (4) Forensic Medicine (including Toxicology). These subjects may be taken separately under certain conditions.

Candidates for the Final Examination must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a printed dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his dissertation shall have been recommended by the Faculty of Medicine to the Council for acceptance. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; and (6) Pathology and Bacteriology.

Communications should be addressed to the Registrar, The University, Manchester.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of registration with the General Medical Council. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other school or schools of medicine recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations. For the present the University will recognise any one of the following examinations, in lieu of its own Matriculation, in the case of medical students, provided always that such examination shall have included the subjects of English, Latin, Mathematics, and any one of the following: Greek, French, German, or any other modern foreign language, together with Chemistry or Experimental Mechanics, or some other branch of Experimental Physics, and that all the subjects have been passed at one examination: (*a*) the previous examination of the University of Cambridge; (*b*) responsions of the University of Oxford; (*c*) the Preliminary or Matriculation Examination of any recognised University; (*d*) the (Higher) Certificate of the Oxford and Cambridge Examinations Board; (*e*) the Oxford or Cambridge Junior Local Examinations; with First or Second Class Honours, or with Distinctions in two subjects, which may be either languages or mathematics; (*f*) the Oxford or Cambridge Senior Local Examination; (*g*) the College of Preceptors' Examination for First Class Certificate. A Matriculation Examination will be held on Sept. 24th, 1906, and succeeding days. First Examination.—Chemistry and Physics and Elementary Biology. Second Examination.—Anatomy and Physiology. Third Examination.—Pathology and Bacteriology, Materia Medica and Practical Pharmacy. Fourth Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, and Public Health. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Gynæcology, Therapeutics, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital and lunatic asylum. Vaccination instruction must be taken out and courses of Ophthalmology, Medical and Surgical Anatomy and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both.

Candidates for either of these degrees will be required to comply with the following regulations. Every candidate for the degree of M.D. shall present a thesis embodying observations in some subject embraced in one of the departments of the medical curriculum enumerated below, and in

---

[1] The following examinations are accepted in lieu of this:—1. The Board will grant exemption from the Matriculation Examination to graduates of any university of the United Kingdom, provided Latin has formed part of one of the degree examinations. 2. For particulars of the conditions under which holders of Certificates from the Universities of Oxford and Cambridge are entitled to exemption, the Calendar of the Joint Matriculation Board should be consulted. 3. Provided that the Certificate shows that all the subjects required by the General Medical Council have been included, the Board is prepared to receive applications for exemption from persons who hold Certificates of having passed the London Matriculation Examination. The fee for registering external Certificates when exemption is granted is £1.

25 meetings on Practical Pharmacy in a university or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. The candidate must have attended for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or of a physician or surgeon, or of a member of the London or Dublin Society of Apothecaries. He must have acted as clerk in the medical wards and dresser in the surgical wards of a public hospital for a period of six months in each case; and must also have availed himself, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying at a hospital or dispensary, Post-mortem Examinations, Fevers, Diseases of the Eye, Operative Surgery, and one of the three following, viz.—Diseases of Children; Diseases of the Larynx, Ear, and Nose; and Diseases of the Skin, or such other special departments as may from time to time be determined. The candidate must have attended, under the superintendence of a registered medical practitioner, 12 cases of labour, or such additional number as the Senatus, with the sanction of the University Court, may from time to time determine; or have attended for three months the practice of a lying-in hospital, or of the maternity department of a general hospital or other public charitable institution and have conducted personally six or such an additional number of cases of labour as the Senatus, with the approval of the University Court, may from time to time determine. The candidate must have been properly instructed in Vaccination at a public vaccination station, by a public vaccinator, authorised by the proper Government authority to grant certificates of proficiency in vaccination.

With respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study, 16 in number—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than eight must be taken in the University of Edinburgh or in some other university of the United Kingdom, or in some Foreign or Colonial university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court, or in a college incorporated with, or affiliated to, a university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court.

Women are admitted to graduation in medicine under practically the same conditions as men, excepting that, until provision is made in the University for instruction of women in all subjects of the medical curriculum, the regulations as to places of study contained in the foregoing paragraph do not apply to them. The Medical College for Women, 30, Chambers-street, Edinburgh, has been recognised as a medical school whose courses of instruction qualify for graduation.

Each candidate is examined, both in writing and orally, and clinically where the nature of the subject admits:—First, in Chemistry, Zoology, Botany, and Physics; second, in Anatomy, Physiology, Materia Medica, and Therapeutics; third, in Pathology; and fourth, in Surgery, Medicine, Midwifery, Forensic Medicine, and Public Health, and clinically in Medicine and Surgery in a hospital. The examinations are conducted, as far as possible, by demonstrations of objects placed before the candidates. Candidates who profess themselves ready to submit to an examination in the first division of these subjects may be admitted to examination therein at the first period of examination after they have completed their attendance on the necessary classes. Candidates who have passed their examination in the first division of these subjects may be admitted to examination in the second division at the end of their third winter session. Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in the third division at the end of the fourth winter session. Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division when they have completed the fifth year of study.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2*s.*, and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6*s.*; for the Second Division (Anatomy, Physiology, and Materia Medica and Therapeutics), £6 6*s.*; for the Third Division (Pathology), £2 2*s.*; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, and Forensic Medicine and Public Health), £8 8*s.* Bachelors of Medicine and Bachelors of Surgery may proceed to the degrees of Doctor of Medicine and Master of Surgery after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £10 10*s.*, and the fee to be paid for the degree of Ch.M. is £10 10*s.*

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but eight of the subjects other than clinical must be taken in this or some other recognised university entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations six degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; and D.Sc. in Public Health. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, with possible options to students whose native language is not English in the case of the fourth subject. Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination but must do so at not more than two occasions.

For the degrees of M.B. and Ch.B. a curriculum of five years is required, in each of the first four of which the student must attend at least two five months' courses, or alternately one five months' course and two courses of two and a half months. The minimum of attendance in the first four years includes five months' courses in the following subjects:—Anatomy, Practical Anatomy (two courses), Chemistry, Materia Medica and Therapeutics, Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women and Infants, and Pathology; and courses of two and a half months in the following: Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Medical Jurisprudence, and Public Health. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted as clerk in medical and dresser in surgical wards, and must have had six months' out-door practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 12 cases of labour, or three months of the Practice of a Lying-in Hospital, six cases being personally conducted The University also requires further study in Post-Mortem Examinations, Fevers, and Ophthalmology, and recommends study in other special subjects. If a candidate has completed in a University of the United Kingdom a course of study and passed an examination in Botany, Zoology, Physics, or Chemistry, qualifying for a degree in Science or in Arts, he is held to have passed the examinations in such subject or subjects.

always that original work published in scientific journals or in the Proceedings of learned societies, or separately, shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree. Candidates will be required to write a short extempore essay on some topic connected with medicine and to answer questions on the history of medicine. They will also be examined orally on the dissertation or other work submitted. Any candidate may be exempted from a part or the whole of the examination if the Board of the Faculty so decide. No candidate will be admitted to the degree unless his application, after report from the Board of the Faculty of Medicine, shall have been accepted by the Senate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Every candidate is also required to furnish certificates of attendance in accordance with the regulations of the University. The subjects of examination are as follows: Surgical Anatomy, Surgery, Operative Surgery, Clinical Surgery, Ophthalmology, Pathology, and Bacteriology.

UNIVERSITY OF SHEFFIELD.

Candidates for a medical degree shall have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board. The subjects required by the General Medical Council must be included in the Matriculation Examination.

The Degrees in the Faculty of Medicine shall be Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate for the degrees of M.B., Ch.B., shall produce certificates that he will have attained the age of 21 years on the day of graduation; that he has pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his registration as a medical student by the General Medical Council, three of such years at least having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the First Examination.

The First Examination.—The subjects of examination are chemistry, physics, and biology. The examination is divided into two parts, A (chemistry and physics) and B (biology), and candidates may pass in each part separately. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and registration as a medical student, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology, for one year each.

The Second Examination.—The subjects of examination are anatomy, physiology, materia medica, and pharmacy. The examination is divided into two parts, A (anatomy and physiology) and B (materia medica and pharmacy), and candidates may pass in either part separately. Candidates must have completed the third winter session of professional study, must have passed the first examination, and must have attended (1) lectures on anatomy and dissections during two winter sessions and one summer session; (2) lectures on physiology during two winter sessions, practical physiology during two winter sessions, and histology during one summer session; and (3) materia medica and pharmacy for three months.

The Third or Final Examination.—The subjects of examination are divided into two parts—namely, A (forensic medicine and toxicology, public health, and pathology and morbid anatomy) and B (medicine, including pharmacology and therapeutics, mental diseases, and diseases of children, surgery, obstetrics, and gynæcology). Candidates may present themselves for examination in both parts on the same occasion or separately, but Part A may not be passed before the completion of the fourth year of study. Candidates for the whole examination or for Part B must have completed the fifth year of study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates for the degree of Ch.M. must have passed the examination for the degrees of M.B., Ch.B. at least one year previously and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution, affording full opportunity for the study of Practical Surgery.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

A diploma in Tropical Medicine and Hygiene (D.T.M. and H.) is granted to graduates in Medicine and Surgery of the University of not less than six months' standing. The course of study includes (1) Practical Bacteriology; (2) Diseases of Tropical Climates; (3) Tropical Hygiene; (4) a Practical Course in Medical Entomology and Protozoology and Venomous Animals; and (5) a Course of Clinical Instruction in Tropical Diseases. Any two of these courses may be taken under Extra-academical Teachers and exemption from the latter course may be granted to those graduates who have been engaged for a period of at least 12 months in the treatment of Tropical Diseases in any tropical or subtropical country. The examinations for the diploma, which will embrace all the foregoing subjects, are held in January and July of each year.

A special University certificate in Diseases of Tropical Climates is also granted to qualified medical practitioners and others specially interested, after approved attendance on the courses of instruction in Tropical Diseases and Practical Bacteriology, including the Micro-organisms of Tropical Diseases.

Before commencing his medical studies each student must pass a preliminary examination in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek or French or German: Provided always that, in the case of a candidate whose native language is not English, an examination in the native language of the candidate may be substituted for one in either French or German, and an examination in any other classical language for one in Latin or Greek.

No one is admitted to the degrees of *Bachelor of Medicine and Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least 100 lectures, or 50 lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months. These courses may be conducted by the professor of clinical surgery, or by professors or lecturers appointed for the purpose by the University Court, or by the ordinary surgeons of the Royal Infirmary, Edinburgh, or of a general hospital defined and recognised as hereinbefore provided, and shall consist of regular instruction at the bedside, along with clinical lectures. A similar course of clinical medicine during a course or courses extending over not less than nine months is required. The candidate must have attended a course of instruction in Mental Diseases given by the University Lecturer, or by a recognised Teacher, consisting of not less than six Class-room meetings for lectures and demonstrations and ten meetings in the Wards of a recognised Asylum for the insane. The candidate must have attended a course of

Medica; third, in Pathology, and Forensic Medicine and Public Health; and fourth, in Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 10 guineas, exclusive of any stamp duty which for the time may be demanded. The fee to be paid for the degree of Master of Surgery shall be 10 guineas.

The whole medical curriculum can be taken in University College or the first two years in United College.

Bursaries, United College, St. Andrews.—Fourteen Taylour Thomson Bursaries for female Medical students of the annual value of from £20 to £30 each, tenable for one or two years. The Bursaries are awarded in the order of merit, the most valuable ones being given to those students who obtain the highest marks in the Preliminary Examination and who are prepared to take two Anni Medici at the United College, St. Andrews.

University College, Dundee.—(*a*) Open to either sex. Eleven Entrance Bursaries of £15, tenable for one year. (*b*) Open to either sex: Four £20 and three £15, second year. (*c*) Four £20 and two £15, third year. (*d*) Bute Bursary, founded in 1893 by the late Most Honourable the Marquis of Bute, K.T. This Bursary consists of the free proceeds of £1000. (*e*) Two Bursaries of the annual value of £25, tenable for three years at either University College, Dundee, or at any Scottish University (local candidates only).

For further particulars apply to the Dean of the Medical Faculty, University College, Dundee, N.B.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must pass a matriculation examination, for which a fee of 5*s*. is payable. No student can be admitted for the winter course after Nov. 25th.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be concurrent with the medical course and the B.A. degree need not be taken before the final medical examinations, but the medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Systematic, Practical and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics, Physiology and Practical Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Dublin Hospital (one year at a recognised London or Edinburgh hospital before the commencement of the Dublin curriculum may be counted as one year spent in such Dublin hospital); (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 30 cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany and Zoology. The Intermediate Medical Part I., including Anatomy and Institutes of Medicine (Practical Histology and Physiology). The Intermediate Medical Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica, Jurisprudence, and Pathology; and Part II., Medicine, Surgery, Midwifery, Gynæcology, Clinical Medicine, Mental Diseases, Clinical Surgery, Operations, and Clinical Ophthalmology. Part I. may be passed in the fourth year and Part II. in the fifth year. Fee for the *Liceat ad Examinandum*, £10. Fee for the degrees, £17.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also read a thesis before the Regius Professor of Physic. Total amount of fees for this degree, £13.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass an examination in the following subjects:—1. Clinical Surgery. 2. Operative Surgery. 3. Surgical Pathology. 4. Surgery. 5. Surgical Anatomy (on the dead subject), and one of the following optional subjects:—1. Surgery in one of the following branches—viz., Ophthalmic and Aural, Gynæcological and Dental. 2. Mental Disease. 3. Medical Jurisprudence and Hygiene. 4. Advanced Anatomy and Physiology. 5. Comparative Anatomy. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must be fully qualified and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery. He is then required to pass an examination in the following subjects:—1. Practice of Midwifery. 2. Gynæcology. 3. Anatomy of Female Pelvis and Elementary Embryology. 4. Clinical Gynæcology. Fee for the degree of Master in Obstetric Science, £5.

University Diplomas.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine and must have completed two years in Arts and five years in Medical Studies. The Course and Examination necessary for the diplomas are the same as for the degrees, except that the candidate is not required to attend the Lectures on Botany and Zoology, nor to pass the Previous Medical examination in those subjects. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the Lectures on Botany and Zoology, passing the Previous Medical examination in those subjects, and paying the degree fees. Fee for the *Liceat ad Examinandum*, £10. Fee for the diplomas in Medicine, Surgery, and Midwifery, £11.

ROYAL UNIVERSITY OF IRELAND.

All Degrees, Honours, Exhibitions, Prizes, Scholarships, and Studentships in this University are open to students of either sex.

Candidates for any degree in this University must have passed the Matriculation Examination. Students from other universities and colleges are included in this rule.

The following degrees, &c., are conferred by the University in this Faculty:—Bachelor of Medicine, Doctor of Medicine, Bachelor of Surgery, Master of Surgery, Bachelor of Obstetrics and Master of Obstetrics; in Sanitary Science, a special diploma; and in Mental Disease, a special diploma.

The course for degrees in Medicine, &c., is of at least five years' duration.

The First Examination in Medicine.—Students may be admitted to this examination after the lapse of one academical year from the time of their matriculation. They must also have previously passed the First University Examination and completed the first year of the medical curriculum. The subjects of this examination are Natural Philosophy, Systematic Chemistry, Zoology and Botany. The examination in each subject will comprise three parts:—(1) a written examination; (2) an oral examination; and (3) a practical examination. Particular weight will be given to the practical part of the examination. Candidates at the First Examination in Medicine who at the First University Examination did not obtain 30 per cent. of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent. of the marks assigned to either of those languages will involve the loss of the examination.

The Second Examination in Medicine.—Students will be admitted to this examination after the lapse of one medical year from the time of passing the First Examination in Medicine, provided they have completed the second year of the medical curriculum. The subjects for this examination are Anatomy, Physiology, and Practical Chemistry.

The Third Examination in Medicine.—Students will be admitted to this examination after the lapse of one medical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of the medical curriculum. The subjects for this

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, to be taken after the completion of the included courses (candidates being at liberty to take two subjects at a time); the second comprising Anatomy, Physiology, and Materia Medica and Therapeutics, to be taken at the end of the third winter session; the third comprising Pathology, Medical Jurisprudence, and Public Health, to be taken at the end of the fourth winter session; and the fourth or final, comprising Surgery, Clinical Surgery, Practice of Medicine, Clinical Medicine, and Midwifery, to be taken on completion of the fifth year of study.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The Fees for M.B. and Ch.B. are £23 2*s.* The class fee in each subject of the curriculum for M.B. and Ch.B. is £2 2*s.*, £3 3*s.*, or £4 4*s.*, and the present fees for hospital attendance are £10 10*s.* The fee for M.D. is £10 10*s.* (stamp duty being now abolished), and for Ch.M. £10 10*s.*

During last academic year there were 657 men and 63 women attending University courses in the Faculty of Medicine—a total of 720. The great majority of the students take their hospital course at the Western Infirmary, where clinical instruction is given by professors of the University and other physicians and surgeons. Clinical instruction on Fevers is given at Ruchil and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, and Insanity. Queen Margaret College, hitherto conducted as a separate institution for the higher education of women, has now been made over to the University and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary. Since 1894, the year in which the University first conferred degrees on women, 126 women have graduated in Medicine.

Bursaries and Prizes to the annual amount of over £1000 are appropriated to medical students, and Scholarships and Fellowships to the annual amount of about £1600 may be held by medical students who have gone through the Arts course.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the Universities of Edinburgh and Glasgow.

Professional Examinations are held twice in each year—namely, in March and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1 1*s.*; summer session alone, 10*s.* 6*d.*

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions (daily), Royal Lunatic Asylum, Ophthalmic Institution, &c.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination. The diploma can be entered on the Register of the General Medical Council.

Application for further information should be addressed to the Secretary of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE, ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

The following are extracts from the Regulations for Degrees in Medicine contained in Ordinance No. 45 (St. Andrews, No. 4) of the Commissioners under the Universities (Scotland) Act, 1889. These regulations came into force on April 19th, 1897. Four degrees in Medicine and Surgery shall be conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical studies each student shall pass a *Preliminary Examination* in (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects:—(α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other Modern Language, (ζ) Logic. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial or foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of L.L.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. *Additional subjects* of study are Practical Pharmacy, Mental Diseases, Practical Midwifery (12 cases of labour), Vaccination, Children's Diseases, Fevers, Ophthalmology, and *Post-mortem Examinations.*

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court.

Women shall be admitted to graduation in Medicine, subject to the provisions of Ordinance No. 18 [General No. 9—Regulations for the Graduation of Women and for their Instruction in the Universities]: Provided always that every candidate for graduation shall produce evidence of having satisfied the conditions herein laid down with respect to the Preliminary Examination, and shall be examined in all the subjects necessary for graduation by the Examiners of the University of St. Andrews. All the classes necessary for graduation shall be taken in the University of St. Andrews, except in so far as instruction obtained elsewhere is allowed by the said Ordinance.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy, Physiology, and Materia written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., 14 clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry, Physics, Elementary Biology, and Practical Pharmacy. A candidate may take this examination in three parts at different times (Chemistry and Physics must be passed together). A candidate will be admitted to examination in Chemistry and Physics, in Practical Pharmacy, and Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution, *or he may take Pharmacy* at any time during the curriculum. (*Note:* In the case of students who commence their professional studies after June 1st, 1904, certificates must be produced of 180 hours' instruction and laboratory work in chemistry; 120 hours' instruction and laboratory work in physics; and 120 hours' instruction and laboratory work in biology. These courses need not be completed within one year, nor need they run concurrently, and they may be commenced or attended before the candidate passes the required preliminary examination in general education.) Synopses of the subjects of examination may be obtained on application. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised Institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a *university* in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

The fees for admission to the First Examination are as follows: For the whole examination, £10 10*s.*; *for* re-examination after rejection in Parts I. and II., £3 3*s.*; and for re-examination in each of the other parts, £2 2*s.*

The subjects of the Second Examination are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the Second Examination at the expiration of two winter sessions and one summer session (or 15 months during the ordinary sessions) from the date of passing Parts I., II., and III. of the First Examination on production of the required certificates of professional study. The study of Anatomy and Physiology before passing the First Professional Examination is not recognised.

A candidate referred on the Second Examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and *Physiological* studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the Second Examination are: *£10 10s.* for the whole examination and £6 6*s.* for re-examination after rejection.

The subjects of the Third or Final Examination are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the First Examination will not be re-examined in that subject at the Third Examination. Part II. Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III. Midwifery and Diseases Peculiar to Women. Candidates may present themselves for examination in Midwifery and Diseases of Women at any time after the completion of the fourth year of professional study at a Medical School and Hospital, not less than one year after passing the Second Examination, on production of the required certificates. Candidates may present themselves for examination in Medicine and Surgery at the completion of the five years' curriculum, not less than two years from the date of passing the Second Examination, on production of the required certificates. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time. They will be required to produce the following evidence before being admitted to the several parts of the Third or Final Examination—viz., in Medicine, of having attended Lectures on Medicine, Pathology including Bacteriology, Pharmacology, and Therapeutics, Forensic Medicine, and Public Health; Practical Instruction in Medicine; Medical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post-mortem Room during 12 months; Clinical Lectures on Medicine during nine months; of having discharged the duties of Medical Clinical Clerk; Instruction in the Administration of Anæsthetics; Practice of a Fever Hospital and Clinical Demonstrations at a recognised Lunatic Asylum; in Surgery, of having attended Lectures on Surgery and Pathology including Bacteriology; Practical Instruction in Surgery; of having performed operations upon the Dead Subject; Surgical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post-mortem Room during 12 months; Clinical Lectures on Surgery during nine months; of having discharged the duties of Surgical Dresser; Instruction in the Administration of Anæsthetics; and Clinical Instruction in Ophthalmology; in Midwifery of having attended Lectures on Midwifery; Practical Instruction in Midwifery; Clinical or other Lectures, with Practical Instruction in Diseases Peculiar to Women; and of attendance on 20 Labours.

The fees for admission *to* the *Third or Final* Examination are as follows: For the whole examination, £21. Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5*s.*; for re-examination in Practical Pharmacy (if taken at this examination), £2 2*s.* Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances, £5 5*s.* Part III. For re-examination in Midwifery and Diseases Peculiar to Women, £3 3*s.*

A candidate referred on the Third or Final Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology, on production of the required certificates.

Graduates in Medicine of certain recognised Indian, Colonial, and Foreign universities may present themselves for the Final examination under special conditions which can be ascertained on application to the Secretary.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or in Edinburgh and Glasgow, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. *Copies of the Regulations for the Single* Licence of any of the Bodies may be had on application to the respective secretaries.

REGULATIONS FOR CANDIDATES WHO COMMENCED STUDY *before* JAN. 1ST, 1892.

Professional Education.—1. The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of examination will be Anatomy, Physiology, and Materia Medica (Pharmacology and Therapeutics).

The Examination for the Medical Degrees.—Students will be admitted to this examination after the lapse of not less than one medical year from the time of passing the Third Examination in Medicine, provided they have completed the course of medical studies prescribed for the entire medical curriculum. The examination consists of three parts or divisions:—(*a*) Medicine, including Therapeutics and Pathology, Mental Diseases, Medical Jurisprudence and Sanitary Science. (*b*) Surgery, Theoretical, Clinical, Operative; Surgical Anatomy, with Ophthalmology and Otology; Surgical Pathology. (*c*) Midwifery and Diseases of Women and Children. Each part of this examination must be passed as a whole. Upon completing satisfactorily his examination in all three divisions the candidate will, in addition to the parchment diplomas recording his admission to the Medical Degrees of M.B., B.Ch., and B.A.O., receive a certificate of having passed a qualifying examination in the subjects of Medicine, Surgery, and Midwifery. The fee for this certificate is £10, which must be paid prior to the candidate's admission to these Degrees.

The M.D. Degree.—Candidates may present themselves for the examination for this degree after the lapse of three academical years from the time of obtaining the degrees of M.B., B.Ch., B.A.O. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising thereon.

The M. Ch. Degree.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination for this degree will comprise Surgical Diseases and Surgery, both theoretical and operative; Surgical Anatomy; Ophthalmology and Otology; Surgical Pathology; and will include—(*a*) a written examination; (*b*) a clinical examination; (*c*) an examination on Surgical Instruments and Appliances; and (*d*) an examination in Operative Surgery.

The M.A.O. Degree.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children, Pathology, and the Use of Instruments and Appliances and will include—(*a*) a written examination; (*b*) a clinical examination as far as practicable; and (*c*) an oral examination, with practical illustrations.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Membership.—Every candidate for the Membership of the College must furnish proof of having attained the age of 25 years. Candidates must not be engaged in trade, dispense medicine, make any engagement with a chemist, or any other person for the supply of medicine, or practise medicine or surgery in partnership, by deed or otherwise. Any candidate being already registered or having passed a qualifying examination in accordance with the Medical Act of 1886, who has obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British colony, or who has obtained a foreign qualification entitling him to practise medicine or surgery in the country where such qualification has been conferred, wherein the courses of study and the examinations to be undergone previously to graduation have been adjudged by the Censors' Board to be satisfactory, will (if the Censors think fit) be admitted to the Pass Examination. The nature and extent of this examination will, in the case of each candidate, be determined by the Censors' Board. All other candidates must produce proof of having passed the examinations required for the Licence of the College. The fee for admission as a Member of the College is 40 guineas, except when the candidate for Membership is a Licentiate of the College, in which case the fee is 25 guineas.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology and the questions on these subjects may require an elementary acquaintance with Comparative Anatomy and Physiology. The examination is partly written and partly *vivâ voce*. The subjects of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examination is partly written and partly *vivâ voce* and includes the examination of patients and the performance of operations on the dead body. The examinations are held during the months of May and November of each year.

The fees for examination are:—First Examination, each admission, five guineas. Second Examination, each admission, 12 guineas. Of such examination fees 17 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a member of the College is admissible to the first Professional Examination for the Fellowship on the production of evidence of having passed the First and Second Examinations of the Examining Board in England by the Royal College of Physicians of London and the Royal College of Surgeons of England (or, if a member of a University, of having passed the Examinations in his University recognised as equivalent to the First and Second Examinations of the Board) and on the production of certificates of attendance upon certain courses of study described in the Regulations. A Colonial, Indian, or Foreign Student, not registered by the General Medical Council, must produce a certificate of having passed such examination or examinations as may, on special application to the Council, be considered as satisfactory.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Secretary of the Examining Board, Examination Hall, Victoria Embankment, London, W.C.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.[2]

Any candidate who desires to obtain both the Licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth. Six months of the curriculum may be spent in an Institution recognised by the Board for instruction in Chemistry, Physics, Practical Chemistry, and Biology.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly

---

[2] The diploma of Member of the Royal College of Surgeons of England and the Licence of the Royal College of Physicians of London are no longer granted separately except to students who commenced their professional study prior to Oct. 1st, 1884.

Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface markings, &c. The fees payable for the Final examination shall be,—for the whole examination, £15, for re-entry in all subjects after rejection, £5.

Candidates who enter on the footing of having passed the earlier examination at another Board shall pay the fees in respect of these examinations, as well as the Final examination fees.

There are six periods of examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespectively of the place of the previous examination. The Registrar in Edinburgh is Mr. J. Robertson, solicitor, 54, George-square; and the Registrar in Glasgow, Mr. A. Duncan, LL.D., 242, St. Vincent-street, to whom fees and certificates must be sent.

Note.—In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan. 1st, 1892.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College of Surgeons of Edinburgh admits to the examination for its single Licence any candidate who already holds a Diploma in Medicine of any British, Indian, or Colonial university or of any British or Colonial College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are now admitted to the Licence of the College but not to the Fellowship, and the regulations for the Licence apply to practitioners of either sex.

Every candidate for a surgical diploma must have followed his course of study in a university, or in an established school of medicine, or in a provincial school specially recognised by the College of Surgeons of that division of the United Kingdom in which it is situate.

Under the title Established School of Medicine are comprehended the medical schools of those cities of Great Britain and Ireland in which Diplomas in Surgery are granted, and such colonial and foreign schools as are similarly circumstanced in the countries in which they exist.

PROFESSIONAL EXAMINATION FOR THE DIPLOMA OF THE COLLEGE.

Candidates for the Diploma of the College will be subjected to one professional examination, partly in writing and partly practically and orally.

Opportunities for the examinations will be presented four times in each year. On each of these occasions the candidates will assemble to write answers to the questions proposed, and the clinical and oral examinations shall be conducted on the days immediately succeeding.

Unsuccessful candidates will be remitted to their studies for a period to be determined by the judgment of the examiners, but not in any case for less than three months.

The examination will embrace the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and will not take place before the termination of the full period of study.

Applications for examination must be made to Mr. James Robertson, solicitor, 54, George-square, Edinburgh, clerk to the College, not later than one week prior to the date of examination.

On the production of the required document Mr. Robertson will give the candidate an order authorising the examiners to admit him to examination.

The fee of £15 15*s.* payable to the College must be lodged in the hands of Mr. Robertson not later than one week preceding the examination day. The sum of £10 10*s.* will be returned to each unsuccessful candidate. Under special circumstances candidates can be examined on days other than those fixed by the regulations. The fee for a special examination is as follows, viz., £20 for examination, of which £10 will be returned to candidates remitted on examination.

In order to test more effectually the practical knowledge of candidates recent dissections and anatomical specimens will be employed during examination. They will also be subjected to a practical clinical examination in the Surgical Hospital, including the application of surgical apparatus, bandages, surface markings, &c., and may, if it be considered necessary to test their knowledge, be required to perform operations on the dead body.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

The Royal College of Physicians of Edinburgh grants its single Licence on terms similar to those of the Royal College of Surgeons of Edinburgh, as above mentioned.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to practise Medicine, £15 15*s.* Fee for examination for the Licences in Medicine and Midwifery, if obtained within the interval of a month, £16 16*s.* —to be lodged in one sum. Any candidate who has been rejected at the examination for the Licence in Medicine loses this privilege and will be required to pay the full fee of five guineas for the Licence in Midwifery. Fee for special examination for the Licence to practise Medicine, £21. Fee for examination for the Licence to practise Midwifery, £5 5*s.* Fee for special examination for the Licence to practise Midwifery, £10 10*s.* The examinations for these Licences are held in the week following the first Friday in February, May, and November.

The Membership.—Examinations for Membership are held in January, April, July, and October. The fee for the examination is £21 to Licentiates of the College, or £36 15*s.* to non-Licentiates. Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—Candidates who hold registrable surgical diplomas (including the Licence of the Apothecaries Companies of London and Dublin granted since October, 1886) are admitted to examination without further evidence of study. Candidates who hold medical qualifications only (including the L.S.A. granted before October, 1886) will be required to produce certificates of two courses of lectures in Anatomy and Dissections, one course of Practical Histology, one course of lectures in Surgery, and one course of Operative Surgery. Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery. The examination is partly written, partly *vivâ voce*, and partly practical. The fee is £26 5*s.*, of which £5 5*s.* is retained by the College in the case of unsuccessful candidates.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification. Candidates must produce evidence of (*a*) attendance on a course of lectures on Midwifery and Diseases of Women and Children in some school recognised by the Council; (*b*) attendance on six months' practice in connexion with a recognised lying-in hospital or dispensary for lying-in women and children, and (*c*) of having conducted at least 20 labour cases. The fee for the examination is £15 15*s.*, of which £5 5*s.* is retained by the College in case the candidate is unsuccessful.

Fellowship Examinations.—A candidate for the Fellowship shall make application to the President and Council to be admitted to examination and if the Council decide to entertain that application it shall lie on the table for at least a fortnight for consideration before it is put to the Council for approval. All the required evidences of study or qualification, fees, and testimonials as to character must be submitted previously to the application being considered, and the candidate shall then, if approved by the Council, be admitted to the next Sessional examination or to a special examination if granted by the Council, at such date as the

Instruction: Anatomy, during at least six months; Practical Anatomy, twelve months; Chemistry, six months; Practical or Analytical Chemistry, three months; Materia Medica, three months; Physiology, six months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery and the Diseases of Women and Children, three months; Medical Jurisprudence, three months; Pathological Anatomy, three months. The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 2. The candidate must also produce the following certificates:—(*a*) Of having attended not less than six cases of labour, three of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for 24 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. (*d*) Of having attended for six months (or three months, with three months' hospital clerkship) the practice of a public dispensary specially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations. (*e*) Of having been instructed in the Theory and Practice of Vaccination by a Public Vaccinator authorised to grant certificates of proficiency in vaccination and of having performed operations under the teacher's inspection during a period of not less than six weeks.

Candidates shall be subjected to three Professional examinations, and they may enter either for the whole of an examination or for a division thereof.

First Examination.—The First examination shall embrace the two divisions of (1) Chemistry and (2) Elementary Anatomy and Histology and shall take place not sooner than the end of the first year, including the period of a winter and a summer session. For the whole examination taken at one time the sum of £5 5*s.* must be paid to the inspector of certificates not later than one week preceding it, after which no candidate will be entered. After rejection, for re-entry in all subjects, £3 3*s.*; for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s.*; for entering for one division of subjects separately, £3 3*s.*; and for each re-entry after rejection, £2 2*s.* Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the First examination before any of the boards specified in the Regulations will be exempt from examination in such subjects.

Second Examination.—The Second examination shall embrace the three subjects of (1) Anatomy, (2) Physiology, (3) Materia Medica and Pharmacy, each of which shall constitute a division of the examination and may be entered for separately. The examination shall not take place before the termination of the summer session of the second year of study, including two winters and two summers. The fees for admission to this examination, payable not later than one week before the day of examination, are as follows:—For the whole examination, £5 5*s.*; after rejection for re-entry in all subjects, £3 3*s.*; for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s.*; for entering for one subject separately, £2 2*s.*; and for each re-entry therein after rejection, £2 2*s.* Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the Second examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects.

Final Examination.—The Final examination shall embrace the three divisions of—(1) the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy, and Pathology) and Clinical Medicine; (2) the Principles and Practice of Surgery (including Surgical Anatomy and Surgical Pathology) and Clinical Surgery; (3) Midwifery and Gynæcology, Medical Jurisprudence, and Hygiene (which divisions may be entered for separately at different times); and shall not take place before the termination of the full period of study. The fees for this examination, payable not later than one week before the examination day, are as follows: For the whole examination, taken at one time, in the case of candidates who have passed the First and Second examinations of the board, £15 15*s.*, of which £10 10*s.* shall be returned to unsuccessful candidates. For entering for each of the three divisions of subjects separately, £6 6*s.*, and on re-entry after rejection, £2 2*s.* in respect of each division or part thereof. This rule will also apply to any subsequent rejection. Any candidate admitted to the Final examination, on the footing of having passed in the subjects of the First and Second examinations at a recognised board, shall, on entering, pay the full fee of £26 5*s.*

All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical Use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c.

REGULATIONS FOR CANDIDATES WHO COMMENCED STUDY *after* JANUARY 1ST, 1892.

In addition to the courses above prescribed candidates are required to attend the following courses: Physics, three months; Elementary Biology, three months; Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; and a third year of Hospital Practice with Clinical Instruction (which may include the study of special diseases). A certificate of vaccination from a teacher authorised by the Local Government Board is also required.

The curriculum lasts for five years; the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries. Six months of the fifth year may be passed by the student as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as may be deemed satisfactory by the Committee of Management. The student's regularity of attendance in the wards and out-patients departments of the hospitals and at the post-mortem examinations should be duly ascertained and noted on the certificate.

Candidates shall be subjected to four professional examinations:

First Examination.—The First examination shall embrace the following divisions of subjects—(1) Physics, (2) Chemistry, including Practical Chemistry, and (3) Elementary Biology. The fees payable for admission to the First examination shall be for the whole examination, £5; for each division separately, £2 10*s.*

Second Examination.—The Second examination shall embrace Anatomy and Physiology including Histology; and candidates may be admitted to this examination at the end of the second year of medical study. The fees payable for admission to the Second examination shall be—for the whole examination, £5, and for re-entry after rejection, £3 for both subjects, and £2 if one of the subjects has been passed.

Third Examination.—The Third examination shall embrace Pathology and Materia Medica with Pharmacy. The fees payable for admission to the Third examination shall be—for the whole examination, £5; for re-entry in both subjects after rejection, £3; and £2 if one of the subjects has been passed.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women and of New-born Children; and Medical Jurisprudence and Public Health. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, must be signed by the Dean of the Medical School or other authority. Section I. of the Final examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. includes the Principles and Practice of Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Section I. of the Final examination cannot be passed before the expiration of 45 months after registration as a medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Society. Section II. of the Final examination consists of two Parts. Part I. Clinical Surgery; Part II. Clinical Medicine and Medical Anatomy. Section II. cannot be passed before the end of the fifth year.

The course of study for the Primary examination is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with Demonstrations, 12 months; Physiology, six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School recognised by the Society. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary.

The course of study for the Final examination, Section I., includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of one winter and one summer session; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership, six months; Performance of Surgical Operations on the Dead Body; lectures on Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship, six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynæcology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on 20 Midwifery cases. The course of medical study must extend over the above-mentioned period of 45 months and the offices of dresser or clinical clerk must be held at a hospital, or other institution recognised by the Society.

The course of study for the Final examination, Section II., includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of 12 months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. No candidate is eligible for the Final examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be obtained of the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to Section II. of the Final examination the candidate must produce certificates: (1) of being 21 years of age; (2) of moral character; (3) of the course of medical study; (4) of proficiency in vaccination signed by a teacher authorised by the Local Government Board; and (5) of instruction in the administration of anæsthetics. Candidates intending to present themselves for examination are required to give 14 days' notice. A form for this purpose will be sent on application.

The fee for the Licence is 20 guineas. The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are four professional examinations, the total fees for which amount to 21 guineas. Ladies are eligible for the diploma. Registered medical practitioners will receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualifications and on paying a fee of 10 guineas. If medicine or surgery be required five guineas extra will be charged.

The fees payable for each examination are as follows:—first professional, £5 5*s.*; second, £5 5*s.*; third, £5 5*s.*; final examination, £6 6*s.* If a candidate gives three clear days' notice of his inability to attend he may present himself at the ensuing examination without a further fee. A candidate is allowed for each professional examination which he has completed at any other licensing body except the final. If he has passed in some only of the subjects in a given examination he has to pay the whole of the fee for that examination. The fees for re examination are for each subject £1 1*s.*, except in the subjects of chemistry, pharmacy, surgery, medicine, second anatomy, pathology, physiology, and ophthalmology, the fees for which are two guineas each. The fee for the third and final or final alone is £15 15*s.* when the other examinations have been taken elsewhere. All examination fees are to be lodged in the Sackville-street Branch of the Royal Bank of Ireland to the credit of the Examination Committee. Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40, Mary-street, Dublin, at least 14 clear days before the first day of examination.

There are four examinations—first, second, third, and final. The first three are held quarterly on the third Monday in January, April, July, and October; the finals are held in January and July. The first examination comprises osteology (first anatomy), biology, physics, theoretical and practical chemistry (with an examination at the bench). Pharmacy is put down in this examination, but it may be taken at any of the first three examinations. Candidates holding a Pharmaceutical licence are exempt from this subject. The second examination comprises anatomy of the whole body (including practical dissections), materia medica and therapeutics, physiology and practical histology. The third examination comprises pathology, materia medica if not taken at second examination, medical jurisprudence, and hygiene. The final examination comprises medicine, including clinical and oral, surgery, including operations, clinical and oral, ophthalmic surgery, including clinical and oral, midwifery, and gynæcology.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall in Ireland must before proceeding to the final examination produce evidence of having been registered as medical students for 57 months, also of having attended courses of instruction as follows:—one course each (of six months) of the following: anatomy (lectures), chemistry (theoretical), midwifery, practice of medicine, physiology, surgery, and dissections, two courses of six months each. Courses of three months: materia medica, medical jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in mental disease, pathology, and a course in vaccination. Medico-chirurgical hospital, 27 months to be distributed, at the student's own discretion, over the last four years of his study. The candidate may substitute for nine months in this hospital attendance, six months as a resident pupil. He will be required to present a certificate of having taken notes of at least six medical and surgical cases recorded under the supervision respectively of a physician and surgeon of his hospital. Three months' study of fever—which may be included in his 27 months' hospital attendance—in a hospital containing fever wards, and having taken notes of five cases of fever—viz., either typhus fever, typhoid fever, scarlet fever, small-pox, or measles. Six months'

President may fix. In order that these regulations may be carried out candidates are required to lodge their applications complete with the Registrar at least one month before the date of examination. Sessional Fellowship examinations commence, as far as arrangements permit, on the third Mondays in February, May, and November. Special examinations may be granted at other times by the Council if they see fit, on sufficient cause being shown, except during the months of August and September. Candidates for the Fellowship examination are divided into two Grades: I., Licentiates or Graduates in Surgery of less than 10 years' standing; II., Licentiates or Graduates in Surgery of more than 10 years' standing. Students not either Licentiates or Graduates in Surgery are permitted to present themselves for the *Primary* examination under Grade I.

Grade I.—Candidates are required to pass two examinations — Primary and Final. Candidates may present themselves for the Final examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology.

The subjects for the Final examination are (*a*) Surgery, including Clinical and Operative Surgery; and (*b*) Surgical Pathology.

Grade II.—The subjects for examination are (*a*) Surgical Anatomy; (*b*) Surgery, including Clinical and Operative Surgery; and (*c*) Surgical Pathology.

Fees.—Grade I.:—For Licentiates of the College: for Primary examination, £15 15*s.*; for Final examination, £10 10*s.* For Licentiates in Surgery of other licensing bodies: for Primary examination, £26 5*s.*; for Final examination, £15 15*s.* For Students of the College: for Primary examination, £5 5*s.*; for Final examination, £21. For Students of other licensing bodies: for Primary examination, £10 10*s.*; for Final examination, £31 10*s.* Grade II.:—Licentiates of the College, £26 5*s.*; Licentiates in Surgery of other licensing bodies, £42; extra fee for Special examination, £10 10*s.*

In case of rejection £10 10*s.*, in addition to the special fee, if such has been paid, is retained by the College and is not allowed in the fees of re-examination.

A rejected candidate will not be again admitted to examination until after a period of three months.

Further particulars can be obtained from the Registrar of the College, Stephen's-green, West Dublin.

ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS, IRELAND.

The following Regulations are obligatory on all students commencing on or after Oct. 1st, 1902:—

PRELIMINARY EXAMINATION AND REGISTRATION.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence of having before entering on medical studies, passed a Preliminary Examination in general education recognised by the Royal Colleges. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of 21 years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.

Every candidate is required to pass four Professional Examinations—at the end of the first, second, third, and fifth years respectively of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other Licensing body. All examinations shall be conducted as far as possible by demonstration of objects placed before the candidates.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; and (2) of having attended a course of—(*a*) lectures on Theoretical Chemistry, winter course; (*b*) Practical Chemistry, three months' summer or winter course; (*c*) Elementary Biology; and (*d*) Physics.

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Biology. The fee for this examination is £15 15*s.*

Second Professional Examination.—Candidates are not admissible to this examination before the end of their second winter session. Every candidate is required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination, and certificates of having attended—(1) Anatomical Dissections, two courses of six months; (2) Practical Histology, three months; (3) Lectures on (*a*) Anatomy, six months; (*b*) Physiology, six months; (*c*) Practical Physiology and Histology, three months.

The subjects of the Second Professional Examination are the following:—(1) Anatomy; and (2) Physiology and Histology. The fee for this examination is £10 10*s.*

Third Professional Examination.—Candidates are not admitted to this examination before the end of their third winter session. Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination and, in addition to the certificates required for the Second Professional Examination, certificates of having attended—(*a*) Pathology; (1) Systematic, (2) Practical, three months each; (*b*) Materia Medica, Pharmacy, and Therapeutics, three months; (*c*) Forensic Medicine and Public Health, three months; (*d*) Surgery, six months. Satisfactory evidence must be produced of attendance in fever wards in connexion with the hospital attendance in either the third or a subsequent year.

The subjects for the Third Professional Examination are the following:—(1) Pathology; (2) Materia Medica, Pharmacy, and Therapeutics; (3) Public Health and Forensic Medicine. The fee for this examination is £9 9*s.*

Final Professional Examination.—Candidates may take one or two sections of this examination at the end of the third year but cannot complete it till the expiry of four years from the passing the First Professional Examination. Every candidate is required before admission to produce evidence (1) of having passed the Third Professional Examination; (2) of having attended—(*a*) at a General Hospital for 27 months; (*b*) Clinical Instruction in Ophthalmic and Aural Surgery for three months; (*c*) a Midwifery Hospital or Maternity, six months; (*d*) Vaccination; and (*e*) Clinical Instruction in Mental Diseases, one month; and (3) Courses of Instruction at a recognised medical school in (*a*) Medicine, six months; (*b*) Surgery, six months; (*c*) Operative Surgery, three months; and (*d*) Midwifery (including Diseases Peculiar to Women and to New-born Children), six months.

The subjects for the Fourth Professional Examination are the following:—(1) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (2) Surgery, including Operative Surgery and Ophthalmic Surgery; (3) Midwifery, including Diseases of Women and New-born Children and Vaccination. Every candidate shall produce evidence of having acted as medical clinical clerk and as surgical dresser. Candidates may present themselves for examination in *all* the subjects of the Final Examination at the *same* time or in certain groups of subjects. The fee for this examination is £6 6*s.* Further particulars can be obtained on application to Alfred Miller, Secretary of the Committee of Management, Royal College of Physicians, Dublin.

SOCIETY OF APOTHECARIES OF LONDON.

There are two examinations—Primary and Final. The Final examination is divided into Section I. and Section II. The Primary examination is held quarterly. Final examinations are held monthly.

The Primary examination consists of two parts. Part I. Elementary Biology; Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Materia Medica and Pharmacy. A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application. Evidence of instruction in these subjects must be produced prior to examination. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study. A schedule for the Primary examination, to be obtained of the Secretary, Mr. L. B. Rawling, and Mr. G. E. Gask. Operative Surgery: Mr. R. C. Bailey, Mr. W. McAdam Eccles, and Mr. W. D. Harmer. Midwifery and the Diseases of Women and Children: Dr. F. H. Champneys. Practical Midwifery: Dr. H. Williamson. Pathology: Dr. F. W. Andrewes. Bacteriology (advanced): Dr. E. E. Klein. Chemical Pathology: Dr. A. E. Garrod. Morbid Anatomy and Post Mortems: Dr. T. J. Horder, Dr. Langdon Brown, and Mr. G. E. Gask. Practical Pathology: Mr. F. A. Rose, Dr. H. Thursfield, Mr. R. C. Elmslie, and Dr. Neligan. Ophthalmic Medicine and Surgery: Mr. W. H. Jessop. Diseases of the Eye: Mr. W. H. Jessop and Mr. W. Holmes Spicer. Ophthalmic Demonstrations: Mr. W. Holmes Spicer. Diseases of the Ear: Mr. A. E. Cumberbatch. Diseases of the Larynx: Mr. W. D. Harmer. Orthopædic Surgery: Mr. W. MacAdam Eccles. Diseases of the Skin: Dr. J. A. Ormerod. Diseases of Children: Dr. A. E. Garrod and Dr. H. Morley Fletcher. Medical Electricity and Electro-therapeutics: Dr. H. Lewis Jones. Mental Diseases and Insanity: Dr. T. Claye Shaw. Dental Surgery: Mr. W. B. Paterson and Mr. J. Ackery. Anæsthetics: Mr. R. Gill, Mr. W. F. Cross, and Mr. H. E. G. Boyle. Forensic Medicine: Dr. W. P. Herringham. Descriptive and Surgical Anatomy: Mr. H. J. Waring and Mr. W. McAdam Eccles. Practical Anatomy: Mr. C. E. West, Mr. C. G. Watson, Mr. T. J. Faulder, Mr. R. B. Etherington-Smith, and Mr. H. W. Wilson. General Anatomy and Physiology: Dr. J. S. Edkins. Practical Physiology: Dr. J. S. Edkins, Dr. W. Langdon Brown, and Mr. J. J. Paterson. Materia Medica, Pharmacology, and Therapeutics: Dr. James Calvert. Pharmacology: Dr. F. A. Bainbridge. Biology and Comparative Anatomy: Dr. T. W. Shore. Practical Biology: Dr. T. W. Shore, Mr. F. W. W. Griffin, and Mr. T. S. Lukis. Chemistry: Dr. W. H. Hurtley. *Practical* Chemistry: Dr. W. H. Hurtley and Mr. K. S. Caldwell. *Physics*: Mr. F. Womack. Practical Physics: Mr. F. Womack and Mr. *Lloyd Hopwood*. Botany: Rev. G. Henslow. Public Health: Dr. George Newman. Practical Hygiene and Public Health: Dr. J. K. Warry. Museum Curator: Dr. F. W. Andrewes. Junior Curator: Dr. W. P. S. Branson. Dean of the School: Dr. T. W. Shore. Warden of College: Mr. G. E. Gask.

CHARING CROSS HOSPITAL AND COLLEGE.—This hospital and convalescent home contain 300 beds, a certain proportion of which are set aside for the diseases of children and those special to women. Total fees, including students' club:—For general students: 1. Composition fee, payable in one sum on joining, 115 guineas. 2. Sessional payment system: Entrance fee, 10 guineas. In addition a sum of 15 guineas must be paid at the beginning of every Winter Session and one of 10 guineas at the beginning of every Summer Session so long as the student *remains* in the school. For Dental students: The fees for the two years' curriculum required by dental students may be paid: (*a*) in one sum of 55 guineas on entry; (*b*) in two instalments, one of 31 guineas on entry and the second of 30 guineas at the end of the first twelve months. General students pay proportionally lower fees and are admitted without additional fee to the courses of Clinical Medicine and Surgery. They are entitled to compete for the Scholarships, Gold Medal, Huxley, and Pereira Prizes.

Classes for the Preliminary Scientific and *Intermediate* Examinations of the University of London and for the Primary F.R.C.S. are held at this Medical School. There are also special classes for the practical work for the Department of Public Health and for the Primary F.R.C S.

Staff.—Consulting Physicians: Sir J. Fayrer, Bart., M.D., Dr. Green, Dr. Bruce, and Dr. Abercrombie. Consulting Obstetric Physician: Dr. J. Watt Black. Physicians: Dr. Murray, Dr. Mott, and Dr. Galloway. Physician to Out-patients: Dr. Fenton. Assistant Physicians: Dr. Hunter, Dr. Bosanquet, and Dr. Forsyth. Consulting Surgeons: Mr. R. Barwell, Mr. Bloxam, and Mr. Morgan, C.V.O. Surgeons: Mr. Boyd, Mr. Waterhouse, and Mr. Wallis. Surgeon to Out-patients: Mr. Gibbs. Assistant Surgeons: Mr. Clogg and Mr. Daniel. Obstetric Physician: Dr. Amand Routh. Assistant Obstetric Physician: Dr. T. W. Eden. Physician for Diseases of the Skin: Dr. Galloway. Assistant Physician for Diseases of the Skin: Dr. MacLeod. Physician to the Electrical Department: Dr. Ironside Bruce. Surgeon for Nose, Throat, and Ear: Mr. Waggett. Ophthalmic Surgeon: Mr. Treacher Collins. Orthopædic Surgeon: Mr. Fairbank. Surgeon Dentist: Mr. J. F. Colyer. Physician for Mental Diseases: Dr. Mercier.

Lecturers: Winter Session.—Anatomy: Dr. Christopher Addison. Bacteriology: Mr. Leathem. Biology and Comparative Anatomy: Dr. H. W. Marett Tims. Chemistry and Physics: Dr. H. Forster Morley. Dental Surgery: Mr. J. F. Colyer. Medicine: Dr. H. Montague Murray and Dr. F. W. Mott. Ophthalmology: Mr. E. Treacher Collins. *Physiology* and Histology: Mr. C. F. Myers-Ward. Practical Anæsthetics: Mr. C. Carter Braine. Practical Anatomy: Dr. Christopher Addison. Practical Hygiene: Mr. Leathem and Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Fenton. Practical Midwifery: Dr. T. W. Eden. Practical Physiology: Mr. C. F. Myers-Ward. Practical Surgery: Mr. F. C. Wallis, Mr. H. S. Clogg, *and Mr. Fairbank*. Operative Surgery: Mr. Charles Gibbs. Psychological Medicine: Dr. Mercier. Surgery: Mr. H. F. Waterhouse. Tropical Medicine: Sir Patrick Manson.

Summer Session.—Anatomy: Dr. Christopher Addison. Anæsthetics: Mr. C. Carter Braine. Dental Surgery: Mr. J. F. Colyer. Forensic Medicine: Dr. Fenton. Materia Medica and Practical Pharmacy: Dr. Galloway. Midwifery: Dr. Amand Routh. Pathology: Dr. W. Hunter. Pharmacology and Therapeutics: Dr. Galloway. Anatomy: Dr. Christopher Addison. Practical Chemistry: Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Fenton. Practical Physiology: Mr. C. F. Myers-Ward. Public Health: Dr. H. T. Bulstrode. Toxicology: Dr. H. Forster Morley. Roentgen Ray: Mr. Mackenzie Davidson.

ST. GEORGE'S HOSPITAL.—This hospital contains 350 beds, of which 205 are allotted to surgical and 145 to medical cases. One ward is set apart for Diseases peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

The Winter Session commences on Oct. 1st but students can enter at any time or for any particular course. The Hospital and Medical School are situated at Hyde Park-corner and are readily accessible from all parts of London. Entrance Scholarships in Anatomy and Physiology are awarded at the commencement of each Winter Session. Prizes: The William Brown Exhibition of £100 per annum (tenable for two years) is awarded by examination to a perpetual pupil of the hospital *every second year*. The William Brown Exhibition of £40 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital. Students are permitted to enter the wards of the hospital at any hour. Dresserships to the surgeons and clinical clerkships to the physicians are open without fee to all students of the hospital. A large number of house office appointments are open without *fee to every* perpetual student of the hospital and are *made* strictly in accordance with the merits of the candidates. Special *attention is directed* to the following paid appointments, amongst others, which are open to students after they have held house office:—Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Curatorship of the Museum at £200; Assistant Curatorship at £100; Obstetric Assistantship (Resident) at £50; Demonstratorship of Anatomy at £50; the post of Senior Anæsthetist at £50; *the* posts (2) of Junior Anæsthetists, each at £30. Great attention is paid by members of the staff to individual teaching. A number of special courses are given in which the requirements of university and *other* examinations receive careful attention. The following may be cited as examples:—(1) Elementary Bacteriology; (2) Advanced Bacteriology; (3) Clinical Pathology; (4) Systematic Pathology; (5) *Histological* Pathology and Morbid Anatomy; (6) Operative Surgery; (7) Public Health; and (8) Tropical Diseases. Special test examinations and *classes are* held by members of the staff for all examinations. The *school* possesses an Amalgamation Club, with well-fitted reading-, smoking-, and luncheon-rooms on the hospital premises. Students have the advantage of a well-filled library of medical and scientific books which is kept *thoroughly* up-to-date. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean. Further information may be obtained from the Dean of the Medical School. Mr. F. Jaffrey, Dean.

Staff.—Consulting Physicians: Sir Henry Pitman, *Dr.* W. H. *Dickinson*, Dr. T. T. Whipham, and Sir Isambard *Owen*. Consulting Surgeons: Mr. Holmes, Mr. Pick, and Mr. Hayward.

practical midwifery and diseases of women during the winter or summer of the third or the fourth year at a recognised lying-in hospital or maternity. Three months' practical pharmacy in a recognised clinical hospital or a recognised school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist. Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than 15 days prior to such registration, except in the subjects of physics or biology. This registration is not undertaken by the Hall. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary-street, Dublin.

UNIVERSITY OF BRUSSELS.

British and other practitioners holding registrable qualifications are admitted to the examination for the Doctorate of the University of Brussels without further curriculum. It is essentially a *practitioner's* examination and is separate from that intended for the Belgian students who take up the medical curriculum of the University. The fees are—For matriculation, £8 12*s.*; for 1st Part, £4 4*s.*; for 2nd Part, £4 8*s.*; for 3rd Part, £4 8*s.*; for legalisation of diploma, 8*s.*—total, £22. Candidates who have paid in advance the fees for the three examinations, and are unsuccessful in the first, recover the fees paid for the second and third; those who fail in the second recover the fees paid for the third examination. Unsuccessful candidates are allowed to come up again three months after rejection on payment of examination fees only, provided this second appearance be in the course of the same academical year (October 1st to June 30th), otherwise they must renew the payment of the matriculation fee of £8 12*s.* The examination consists of three parts, viz.—1st Part: General Medicine; Materia Medica and Pharmacology; General Surgery; and Theory of Midwifery. 2nd Part: General Therapeutics; Pathology and Morbid Anatomy, with use of the microscope; Special Therapeutics and Medicine of Internal Diseases, including Mental Diseases; and Special Surgery. 3rd Part: Public and Private Hygiene; Medical Jurisprudence; Clinical Medicine; Clinical Surgery; examination in Operative Surgery, consisting of some of the usual operations on the dead subject—viz., Amputation, Ligature of an Artery, &c.; Ophthalmology; examination in Midwifery, consisting in obstetrical operation on the mannikin (model of pelvis); and examination in Regional Anatomy with Dissection. The time required for the three examinations seldom exceeds ten days, and is usually less. Candidates have the option of passing each part separately or of taking the three together, and the latter is the usual course; also of demanding a written examination on payment of an additional fee of one guinea for each part, a rule of which candidates rarely or never avail themselves. The examinations, which are *vivâ voce*, begin on the first Tuesday in November, December, February, May, and June. Candidates should appear with their diplomas at the Secretary's office not later than 2 P.M. on the day preceding the examination. Most of the examiners speak English and those who do not examine through the medium of an interpreter. Great importance is attached to practical knowledge, but candidates must also possess sound theoretical knowledge, the standard required varying with the subject. Pathological and other specimens are not usually shown. There are in England at present over 600 graduates holding this degree, and a British Association of Brussels Medical Graduates has been in existence for many years. Applications should be made to the Secrétariat, 14, Rue des Sols, Bruxelles.

METROPOLITAN MEDICAL SCHOOLS.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital is large. The hospital contains 744 beds, of which 674 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley.

This hospital receives within its walls more than 7000 in-patients annually and its out-patients and casualties amount to more than 140,000 annually.

Special departments have been organised for diseases of the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery in which Chief Assistants and Clinical Assistants are appointed annually. Surgical operations take place every day at 1.30 P.M. and Surgical Consultations are held on Thursdays at the same hour. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical Lectures on all special subjects are also given. The visits of the physicians and surgeons are made at 1.30.

Ten house physicians and ten house surgeons are appointed annually. During their first six months of office they act as "junior" house physicians and house surgeons and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons and are provided with rooms by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. All the appointments are now free. A college is attached to the hospital.

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pathology, chemical pathology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

The recreation ground of 10 acres is at Winchmore-hill for the use of the members of the Students' Union, which all students are expected to join.

Instruction in Preliminary Science is given to University of London students in chemistry, biology, and physics throughout the year.

Laboratory Instruction for the D.P.H. is provided during the winter and summer sessions, and elementary instruction in Bacteriology is also given throughout the year.

Staff.—Consulting Physicians: Sir William S. Church, Bart., K.C.B., Dr. Hensley, Sir Lauder Brunton, F.R.S., Dr. Gee, and Sir Dyce Duckworth. Consulting Surgeons: Sir Thomas Smith, Bart., K.C.V.O., Mr. Willett, Mr. Butlin, Mr. Marsh, and Mr. Langton. Consulting Ophthalmic Surgeon: Mr. Henry Power. Physicians: Dr. Norman Moore, Dr. Samuel West, Dr. Ormerod, Dr. Herringham, and Dr. Tooth, C.M.G. Surgeons: Mr. Harrison Cripps, Mr. Bruce Clarke, Mr. Anthony Bowlby, C.M.G., Mr. Lockwood, and Mr. D'Arcy Power. Assistant Physicians: Dr. Garrod, Dr. Calvert, Dr. Morley Fletcher, Dr. Drysdale, and Dr. Horton-Smith-Hartley. Assistant Surgeons: Mr. Waring, Mr. Eccles, Mr. Bailey, Mr. Harmer, and Mr. Rawling. Physician Accoucheur: Dr. Champneys. Assistant Physician Accoucheur: Dr. W. S. A. Griffith. Surgeon to Obstetric Wards: Mr. Harrison Cripps. Ophthalmic Surgeons: Mr. Jessop and Mr. Holmes Spicer. Aural Surgeon: Mr. Cumberbatch. Dental Surgeons: Mr. Paterson and Mr. Ackery. Assistant Dental Surgeons: Mr. Ackland and Dr. Austen. Medical Officer in charge of Electrical Department: Dr. Lewis Jones. Pathologist: Dr. Andrewes. Administrators of Anæsthetics: Mr. Gill and Mr. Cross. Assistant Administrator of Anæsthetics: Mr. Boyle. Medical Registrars: Dr. Horder and Dr. Langdon Brown. Surgical Registrar: Mr. Gask. Casualty Physicians: Dr. Branson and Dr. Howell.

Lectures and Demonstrations.—Medicine: Dr. Norman Moore and Dr. S. West. Clinical Medicine: Dr. Norman Moore, Dr. S. West, Dr. J. A. Ormerod, Dr. W. P. Herringham, and Dr. H. H. Tooth. Practical Medicine: Dr. J. H. Drysdale, Dr. Horton-Smith-Hartley, and Dr. W. P. S. Bransom. Surgery: Mr. W. Bruce Clarke and Mr. D'Arcy Power. Clinical Surgery: Mr. Harrison Cripps, Mr. W. Bruce Clarke, Mr. Anthony Bowlby, Mr. C. B. Lockwood, and Mr. D'Arcy Power. Practical Surgery: Mr. R. C. Bailey,

---

[1] For Scholarships see p. 590 et seq.

Mr. L. B. Rawling, and Mr. G. E. Gask. Operative Surgery: Mr. R. C. Bailey, Mr. W. McAdam Eccles, and Mr. W. D. Harmer. Midwifery and the Diseases of Women and Children: Dr. F. H. Champneys. Practical Midwifery: Dr. H. Williamson. Pathology: Dr. F. W. Andrewes. Bacteriology (advanced): Dr. E. E. Klein. Chemical Pathology: Dr. A. E. Garrod. Morbid Anatomy and Post Mortems: Dr. T. J. Horder, Dr. Langdon Brown, and Mr. G. E. Gask. Practical Pathology: Mr. F. A. Rose, Dr. H. Thursfield, Mr. R. C. Elmslie, and Dr. Neligan. Ophthalmic Medicine and Surgery: Mr. W. H. Jessop. Diseases of the Eye: Mr. W. H. Jessop and Mr. W. Holmes Spicer. Ophthalmic Demonstrations: Mr. W. Holmes Spicer. Diseases of the Ear: Mr. A. E. Cumberbatch. Diseases of the Larynx: Mr. W. D. Harmer. Orthopædic Surgery: Mr. W. MacAdam Eccles. Diseases of the Skin: Dr. J. A. Ormerod. Diseases of Children: Dr. A. E. Garrod and Dr. H. Morley Fletcher. Medical Electricity and Electro-therapeutics: Dr. H. Lewis Jones. Mental Diseases and Insanity: Dr. T. Claye Shaw. Dental Surgery: Mr. W. B. Paterson and Mr. J. Ackery. Anæsthetics: Mr. R. Gill, Mr. W. F. Cross, and Mr. H. E. G. Boyle. Forensic Medicine: Dr. W. P. Herringham. Descriptive and Surgical Anatomy: Mr. H. J. Waring and Mr. W. McAdam Eccles. Practical Anatomy: Mr. C. E. West, Mr. C. G. Watson, Mr. T. J. Faulder, Mr. R. B. Etherington-Smith, and Mr. H. W. Wilson. General Anatomy and Physiology: Dr. J. S. Edkins. Practical Physiology: Dr. J. S. Edkins, Dr. W. Langdon Brown, and Mr. J. J. Paterson. Materia Medica, Pharmacology, and Therapeutics: Dr. James Calvert. Pharmacology: Dr. F. A. Bainbridge. Biology and Comparative Anatomy: Dr. T. W. Shore. Practical Biology: Dr. T. W. Shore, Mr. F. W. W. Griffin, and Mr. T. S. Lukis. Chemistry: Dr. W. H. Hurtley. Practical Chemistry: Dr. W. H. Hurtley and Mr. K. S. Caldwell. Physics: Mr. F. Womack. Practical Physics: Mr. F. Womack and Mr. Lloyd Hopwood. Botany: Rev. G. Henslow. Public Health: Dr. George Newman. Practical Hygiene and Public Health: Dr. J. K. Warry. Museum Curator: Dr. F. W. Andrewes. Junior Curator: Dr. W. P. S. Branson. Dean of the School: Dr. T. W. Shore. Warden of College: Mr. G. E. Gask.

CHARING CROSS HOSPITAL AND COLLEGE.—This hospital and convalescent home contain 300 beds, a certain proportion of which are set aside for the diseases of children and those special to women. Total fees, including students' club:—For general students: 1. Composition fee, payable in one sum on joining, 115 guineas. 2. Sessional payment system: Entrance fee, 10 guineas. In addition a sum of 15 guineas must be paid at the beginning of every Winter Session and one of 10 guineas at the beginning of every Summer Session so long as the student remains in the school. For Dental students: The fees for the two years' curriculum required by dental students may be paid: (*a*) in one sum of 55 guineas on entry; (*b*) in two instalments, one of 31 guineas on entry and the second of 30 guineas at the end of the first twelve months. General students pay proportionally lower fees and are admitted without additional fee to the courses of Clinical Medicine and Surgery. They are entitled to compete for the Scholarships, Gold Medal, Huxley, and Pereira Prizes.

Classes for the Preliminary Scientific and Intermediate Examinations of the University of London and for the Primary F.R.C.S. are held at this Medical School. There are also special classes for the practical work for the Department of Public Health and for the Primary F.R.C.S.

Staff.—Consulting Physicians: Sir J. Fayrer, Bart., M.D., Dr. Green, Dr. Bruce, and Dr. Abercrombie. Consulting Obstetric Physician: Dr. J. Watt Black. Physicians: Dr. Murray, Dr. Mott, and Dr. Galloway. Physician to Out-patients: Dr. Fenton. Assistant Physicians: Dr. Hunter, Dr. Bosanquet, and Dr. Forsyth. Consulting Surgeons: Mr. R. Barwell, Mr. Bloxam, and Mr. Morgan, C.V.O. Surgeons: Mr. Boyd, Mr. Waterhouse, and Mr. Wallis. Surgeon to Out-patients: Mr. Gibbs. Assistant Surgeons: Mr. Clogg and Mr. Daniel. Obstetric Physician: Dr. Amand Routh. Assistant Obstetric Physician: Dr. T. W. Eden. Physician for Diseases of the Skin: Dr. Galloway. Assistant Physician for Diseases of the Skin: Dr. MacLeod. Physician to the Electrical Department: Dr. Ironside Bruce. Surgeon for Nose, Throat, and Ear: Mr. Waggett. Ophthalmic Surgeon: Mr. Treacher Collins. Orthopædic Surgeon: Mr. Fairbank. Surgeon Dentist: Mr. J. F. Colyer. Physician for Mental Diseases: Dr. Mercier.

Lecturers: Winter Session.—Anatomy: Dr. Christopher Addison. Bacteriology: Mr. Leathem. Biology and Comparative Anatomy: Dr. H. W. Marett Tims. Chemistry and Physics: Dr. H. Forster Morley. Dental Surgery: Mr. J. F. Colyer. Medicine: Dr. H. Montague Murray and Dr. F. W. Mott. Ophthalmology: Mr. E. Treacher Collins. Physiology and Histology: Mr. C. F. Myers-Ward. Practical Anæsthetics: Mr. C. Carter Braine. Practical Anatomy: Dr. Christopher Addison. Practical Hygiene: Mr. Leathem and Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Fenton. Practical Midwifery: Dr. T. W. Eden. Practical Physiology: Mr. C. F. Myers-Ward. Practical Surgery: Mr. F. C. Wallis, Mr. H. S. Clogg, and Mr. Fairbank. Operative Surgery: Mr. Charles Gibbs. Psychological Medicine: Dr. Mercier. Surgery: Mr. H. F. Waterhouse. Tropical Medicine: Sir Patrick Manson.

Summer Session.—Anatomy: Dr. Christopher Addison. Anæsthetics: Mr. C. Carter Braine. Dental Surgery: Mr. J. F. Colyer. Forensic Medicine: Dr. Fenton. Materia Medica and Practical Pharmacy: Dr. Galloway. Midwifery: Dr. Amand Routh. Pathology: Dr. W. Hunter. Pharmacology and Therapeutics: Dr. Galloway. Anatomy: Dr. Christopher Addison. Practical Chemistry: Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Fenton. Practical Physiology: Mr. C. F. Myers-Ward. Public Health: Dr. H. T. Bulstrode. Toxicology: Dr. H. Forster Morley. Roentgen Ray: Mr. Mackenzie Davidson.

ST. GEORGE'S HOSPITAL.—This hospital contains 350 beds, of which 205 are allotted to surgical and 145 to medical cases. One ward is set apart for Diseases peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

The Winter Session commences on Oct. 1st but students can enter at any time or for any particular course. The Hospital and Medical School are situated at Hyde Park-corner and are readily accessible from all parts of London. Entrance Scholarships in Anatomy and Physiology are awarded at the commencement of each Winter Session. Prizes: The William Brown Exhibition of £100 per annum (tenable for two years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition of £40 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital. Students are permitted to enter the wards of the hospital at any hour. Dresserships to the surgeons and clinical clerkships to the physicians are open without fee to all students of the hospital. A large number of house office appointments are open without fee to every perpetual student of the hospital and are made strictly in accordance with the merits of the candidates. Special attention is directed to the following paid appointments, amongst others, which are open to students after they have held house office:—Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Curatorship of the Museum at £200; Assistant Curatorship at £100; Obstetric Assistantship (Resident) at £50; Demonstratorship of Anatomy at £50; the post of Senior Anæsthetist at £50; the posts (2) of Junior Anæsthetists, each at £30. Great attention is paid by members of the staff to individual teaching. A number of special courses are given in which the requirements of university and other examinations receive careful attention. The following may be cited as examples:—(1) Elementary Bacteriology; (2) Advanced Bacteriology; (3) Clinical Pathology; (4) Systematic Pathology; (5) Histological Pathology and Morbid Anatomy; (6) Operative Surgery; (7) Public Health; and (8) Tropical Diseases. Special test examinations and classes are held by members of the staff for all examinations. The school possesses an Amalgamation Club, with well-fitted reading-, smoking-, and luncheon-rooms on the hospital premises. Students have the advantage of a well-filled library of medical and scientific books which is kept thoroughly up-to-date. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean. Further information may be obtained from the Dean of the Medical School. Mr. F. Jaffrey, Dean.

Staff.—Consulting Physicians: Sir Henry Pitman, Dr. W. H. Dickinson, Dr. T. T. Whipham, and Sir Isambard Owen. Consulting Surgeons: Mr. Holmes, Mr. Pick, and Mr. Hayward.

Consulting Obstetric Physician: Dr. Barnes. Consulting Ophthalmic Surgeon: Mr. Brudenell Carter. Consulting Aural Surgeon: Sir William Dalby. Consulting Dental Surgeon: Mr. Winterbottom. Physicians: Dr. William Ewart, Dr. H. D. Rolleston. Dr. Ogle, and Dr. Latham. Obstetric Physician: Dr. W. R. Dakin. Assistant Physicians: Dr. Collier, Dr. Spriggs, and Dr. Jex-Blake. Assistant Obstetric Physician: Dr. A. F. Stabb. Physician to the Skin Department: Dr. Wyndham Cottle. Physician Anæsthetist: Dr. F. Hewitt. Surgeons: Mr. C. T. Dent, Mr. G. R. Turner, Mr. A. M. Sheild, and Mr. F. Jaffrey. Ophthalmic Surgeon: Mr. H. B. Grimsdale. Assistant Surgeons: Mr. H. S. Pendlebury, Mr. T. Crisp English, and Mr. L. Jones. Surgeon to the Orthopædic Department: Mr. F. Jaffrey. Surgeon to the Throat Department: Mr. H. S. Barwell. Aural Surgeon: Mr. W. C. Bull. Dental Surgeon: Mr. N. G. Bennett. Assistant Dental Surgeon: Mr. Morley.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 602 beds.

House physicians, house surgeons, assistant house physicians and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical and medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical council according to merit and without extra payment. The house physicians, of whom there are four, hold office for six months each. The assistant house physicians, who hold office for three months, attend in the out-patient department five afternoons in the week and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons and there are four out-patient officers appointed each three months. The surgeons' dressers are selected from those students who have completed their third winter session and have been most diligent in the junior appointments. They hold office for three or six months. Six are attached to each surgeon and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, four in number, are provided with board and lodging in the college free of expense. The college stands upon a site fronting the east gate of the hospital and is connected with it by a subway. The building serves as a Residential College for Students and at the same time provides accommodation for the Students' Club.

Medical and Surgical Staff.—Consulting Physicians: Sir Samuel Wilks, Bart., Dr. F. W. Pavy, Dr. P. H. Pye-Smith, and Dr. J. F. Goodhart. Consulting Surgeons: Mr. Thomas Bryant, Sir H. G. Howse, and Mr. Jacobson. Consulting Obstetric Physician: Dr. A. L. Galabin. Consulting Physician for Mental Diseases: Dr. G. H. Savage. Consulting Aural Surgeon: Mr. W. Laidlaw Purves. Consulting Anæsthetist: Mr. Tom Bird. Physicians and Assistant Physicians: Dr. Frederick Taylor, Dr. W. Hale White, Dr. G. Newton Pitt, Sir Cooper Perry, Dr. L. E. Shaw, Dr. J. Fawcett, Dr. A. P. Beddard, and Dr. H. S French. Surgeons and Assistant Surgeons: Mr. C. H. Golding-Bird, Mr. Charters J. Symonds, Mr. W. Arbuthnot Lane, Mr. L. A. Dunn, Sir Alfred Fripp, C.B., C.V.O., Mr. F. J. Steward, Mr. Fagge, and Mr. R. P. Rowlands. Obstetric Physicians: Dr. P. Horrocks and Mr. J. H. Targett. Assistant Obstetric Physician: Mr. G. Bellingham Smith. Ophthalmic Surgeons: Mr. H. L. Eason and Mr. A. W. Ormond. Physician in Charge of Skin Department: Sir Cooper Perry. Physician for Mental Diseases: Dr. M. Craig. Surgeon in Charge of Throat Department: Mr. F. J. Steward. Surgeon in Charge of Aural Department: Mr. C. H. Fagge. Dental Surgeons: Mr. F. Newland-Pedley, Mr. W. A. Maggs, and Mr. R. Wynne Rouw. Anæsthetists: Mr. G. Rowell, Dr. H. F. Lancaster, Mr. C. J. Ogle, Mr. P. Turner, Mr. H. T. Hicks, Dr. D. Forsyth, Mr. W. M. Mollison, and Mr. A. R. Thompson. Medical Registrars and Tutors: Dr. H. F. Bell Walker and Mr. H. C. C. Mann. Obstetric Registrar and Tutor: Mr. H. T. Hicks. Surgical Registrar and Tutor: Mr. R. A. Greeves. Actino-Therapeutic Department: Mr. G. T. S. Sichel. Radiographer: Mr. E. W. H. Shenton. Bacteriologist to the Hospital: Dr. W. H. Eyre. Resident Surgical Officer: Mr. E. C. Hughes, M.B., B.C. Hon. Librarian, Wills Library: Dr. L. E. Shaw. Lying-in Charity: Mr. Targett and Mr. Bellingham Smith. Dean of the Medical School: Dr. H. L. Eason. Warden of the College: W. M. Mollison, M.C.

Lecturers and Demonstrators.—Clinical Medicine: the Physicians and Assistant Physicians. Clinical Surgery: the Surgeons and Assistant Surgeons. Medicine: Dr. Taylor and Dr. Hale White. Practical Medicine: Dr. Bell Walker and Mr. Mann. Surgery: Mr. Golding-Bird, Mr. Symonds, Mr. Lane, and Mr. Dunn. Operative Surgery: Sir Alfred Fripp and Mr. Steward. Practical Surgery: Mr. Greeves. Midwifery and Diseases of Women: Dr. Horrocks and Mr. Targett. Practical Obstetrics: Mr. Hicks. Mental Diseases: Dr. Craig. Ophthalmic Surgery: Mr. Eason. Dental Surgery: Mr. Wynne Rouw. Aural Surgery: Mr. Fagge. Diseases of the Skin: Sir Cooper Perry. Diseases of the Throat: Mr. Steward. Anæsthetics: Mr. Rowell. Hygiene and Public Health: Dr. Sykes. Pathology: Dr. Pitt. Gordon Lecturer on Experimental Pathology: Dr. F. A. Bainbridge. Morbid Anatomy: Dr. Fawcett and Dr. French. Morbid Histology and Bacteriology: Mr. Bellingham Smith and Dr. Eyre. Medical and Surgical Pathology Classes: Dr. Fawcett and Mr. Steward. Bacteriology: Dr. Eyre. Practical Bacteriology: Dr. Eyre. Forensic Medicine: Sir Thomas Stevenson, M.D. Anatomy: Sir Alfred Fripp and Mr. Steward. Practical Anatomy: Mr. P. Turner, Mr. W. M. Mollison, and Mr. A. R. Thompson, M.B, Ch.B. Physiology: Dr. Pembrey. Practical Physiology: Dr. Pembrey, Mr. A. F. Hertz, M.B, B Ch., and Mr. H. C. Cameron, M B., B.C. Materia Medica and Therapeutics: Dr. A. P. Beddard. Practical Pharmacy: the Hospital Pharmacist. Chemistry: Dr. Wade. Practical Chemistry: Dr. Wade, Mr. Ball, and Mr. Merriman. Experimental Physics: Dr. Fison and Mr. Merriman. Biology: Mr. Assheton, Dr. Stevens, and Mr. Thompson. Psychology: Dr. Craig.

KING'S COLLEGE.—The Faculty of Medicine at King's College is now divided into two parts; the first is concerned with Preliminary and Intermediate subjects and instruction on these is given in the College laboratories. This department is now designated Faculty of Science (Medical division); the second deals with the Advanced or Final subjects of the curriculum, instruction on which is given at the hospital, except in subjects like Bacteriology where laboratory courses are necessary.

Lecturers on Preliminary and Intermediate Subjects.—Anatomy: Dr. P. Thompson (Professor) and Dr. C. J. Jenkins (Lecturer). Physiology: Dr. W. D. Halliburton (Professor), Dr. H. W. Lyle (Lecturer), Dr. O. Rosenheim (Lecturer on Chemical Physiology), and Dr. C. S. Myers (Lecturer on Experimental Psychology). Zoology: Dr. A. Dendy (Professor). Botany: Dr. W. B. Bottomley (Professor) and Mr. E. J. Schwartz (Demonstrator). Chemistry: Dr. J. M. Thomson (Professor), Mr. H. Jackson (Assistant Professor), and Mr. P. H. Kirkaldy (Lecturer). Physics: Dr. Wilson. Materia Medica and Pharmacology: Dr. W. E. Dixon (Professor).

Fees.—For London University Course: for Preliminary Scientific (Part I.), 25 guineas; for Preliminary Scientific (Part II.) and Intermediate M.B., 55 guineas, or two instalments of 30 guineas each. For Conjoint Board Course: for First examination, 20 guineas; for Second examination, 55 guineas, or two instalments of 30 guineas each. For prospectus and further information application should be made to Dr. P. Thompson, Dean of the department.

King's College Hospital contains 217 available beds. Resident medical officers have rooms at the hospital and commons free; they are selected by examination and hold their appointment for six months or a year. There are two house physicians, two physician accoucheur assistants, and three house surgeons. Sambrooke registrarships, value £50 per annum, are tenable for two years. There are also senior medical and surgical, and obstetric registrars and tutors, value £50 and £30 per annum respectively. Clinical assistants senior and junior of the special departments—ophthalmic, ear, throat, skin, children, and dental—senior dressers and dressers, clinical clerks, &c., are elected by examination or in consideration of their former work in the Faculty of Science (medical division).

Hospital Staff.—Consulting Physicians: Sir A. B. Garrod, Dr. Alfred B. Duffin, and Dr. I. Burney Yeo. Consulting Surgeons: Lord Lister and Mr. W. Rose. Physicians: Dr. David Ferrier, Dr. Nestor Tirard, Dr. Norman Dalton, Sir Hugh Beevor, Bart., and Dr. Raymond Crawfurd. Surgeons: Mr. W. Watson Cheyne, Mr. A. B. Barrow, Mr. A. Carless, Mr. F. F. Burghard, Mr. G. L. Cheatle, and Mr. P. T. B. Beale. Assistant Physicians: Dr. W. Aldren Turner and Dr. Tunnicliffe. Obstetric Physician: Dr. John Phillips. Assistant Obstetric Physician: Dr. Hugh Playfair. Physician for the Diseases of Children: Dr. George F. Still. Diseases of the Throat: Dr. StClair Thomson. Dental Surgeon: Mr. A. S. Underwood. Assistant Dental Surgeon: Mr. C. E. Wallis. Ophthalmic Surgeons: Mr. M. M. McHardy and Mr. L. V. Cargill. Aural Surgeons: Dr. Urban Pritchard and Mr. Arthur H. Cheatle. Physician for Diseases of the Skin: Dr. A. Whitfield. Pathological Registrar: Dr. Norman Dalton. Physician in charge of Electrical Department: Dr. W. Aldren Turner. Medical Officer in charge of X Ray Department: Mr. A. D. Reid. Anæsthetist and Instructor in Anæsthetics: Dr. J. F. W. Silk. Assistant Anæsthetist: Dr. G. B. Flux. Senior Medical Registrar and Tutor: Dr. J. C. Briscoe. Senior Surgical Registrar and Tutor: Dr. T. Percy Legg. Obstetric Registrar and Tutor: Dr. G. de B. Turtle. Sambrooke Registrars: Mr. H. W. Wiltshire and Mr. R. H. Gompertz. Clinical Pathologist: Dr. Emery.

Lecturers on Final Subjects.—Medicine (Principles and Practice of): Dr. Nestor Tirard (Professor). Neuro-Pathology: Dr. D. Ferrier (Professor) and Dr. W. A. Turner (Demonstrator). Psychological Medicine: Dr. Ernest W. White (Professor). Surgery (Principles and Practice of): Mr. A. Carless (Professor). Surgery (Operative): Mr. F. F. Burghard (Teacher). Surgical Pathology: Mr. G. L. Cheatle (Teacher). Obstetric Medicine and Diseases of Women and Children: Dr. John Phillips (Professor). Practical Obstetrics: Dr. Hugh Playfair (Lecturer). Diseases of Children: Dr. G. F. Still (Professor). Pathology: Dr. N. Dalton (Professor). Forensic Medicine: Dr. W. R. Smith (Professor). Hygiene: Dr. W. J. R. Simpson (Professor). State Medicine: Dr. Hewlett (Professor) and Mr. D. Somerville (Demonstrator). Bacteriology: Dr. Hewlett (Professor) and Dr. F. E. Taylor. Ophthalmic Surgery: Mr. M. M. McHardy (Professor). Aural Surgery: Dr. Urban Pritchard (Professor). Anæsthetics: Dr. J. F. W. Silk. Dental Surgery: Mr. A. S. Underwood (Professor). Diseases of the Skin: Dr. A. Whitfield (Physician).

Fees.—The composition fee for Hospital work and Final subjects of the curriculum is 70 guineas in one sum or in two equal instalments of 36 guineas payable on entrance and on commencement of second year of study respectively. For information and prospectus application should be made to Peyton T. B. Beale, F.R C S , Dean of the Hospital. For information regarding fees, curriculum, &c., in Public Health and Bacteriology application should be made to Professor Hewlett.

Athletic Club.—All students are entitled to the privileges of the Athletic Club, which manages a large recreation ground of the College at Wormwood Scrubs.

LONDON HOSPITAL AND COLLEGE.—The hospital has nearly 929 beds in constant use and *no* beds are closed. Being the only general hospital for East London—i.e., for a million and a half people—the practice is immense. In-patients last year, 13,552; out-patients, 209,272; accidents, 15,719; major operations, 3353. Owing to the enormous number of patients more appointments are open to students than at any other hospital. Receiving-room officers, house physicians, house surgeons, &c.: 90 of these qualified appointments are made annually and more than 150 dressers, clinical clerks, &c., appointed every three months. All are free to students of the College. Holders of resident appointments have free board. Thirty-seven scholarships and prizes are given annually. Seven entrance scholarships, £120, £120, £60, £60, £35, £30, £20, are offered in September. Special classes are held for the University of London and other higher examinations. Special entries for medical and surgical practice can be made. Lectures and classes and held throughout the year to suit the requirements of candidates desirous of obtaining the diploma in Public Health. The Lecturer on Public Health has his offices in the College, enabling the candidates to attend daily to work under his supervision. These courses are recognised both by the Universities of Oxford, Cambridge, London, &c., and by the Examining Board in England. A reduction of 15 guineas is made from the perpetual fee to the sons of members of the profession. The new laboratories and class-rooms for Bacteriology, Public Health, Operative Surgery, Chemistry, and Biology are now in full use. The new Clubs Union Rooms, Garden, and Fives Court are now open. The Clubs Union Athletic Ground is within easy reach of the hospital. The Metropolitan and other railways have stations close to the hospital and the college.

Staff.—Consulting Physicians: Dr. Hughlings Jackson, Dr. Sansom, and Sir Stephen Mackenzie. Consulting Surgeons: Mr. Hutchinson, Mr. Couper, Mr. McCarthy, Sir Frederick Treves, Bart., and Mr. Tay. Consulting Obstetric Physician: Dr. Herman. Physicians: Dr. Francis Warner, Dr. Percy Kidd, Dr. Frederick J. Smith, Dr. W. J. Hadley, Dr. G. Schorstein, Dr. Bertrand Dawson, and Dr. Henry Head. Assistant Physicians: Dr. Robert Hutchison, Dr. Lewis Smith, Dr. Wall, and Dr. Grünbaum. Surgeons: Mr. C. W. Mansell-Moullin, Mr. Hurry Fenwick, Mr. F. S. Eve, Mr. J. Hutchinson, jun., Mr. T. H. Openshaw, Mr. H. P. Dean, and Mr. P. Furnivall. Assistant Surgeons: Mr. H. Barnard, Mr. Rigby, Mr. Sherren, and Mr. Lett. Obstetric Physician: Dr. Lewers. Assistant Obstetric Physician: Dr. Andrews. Physician to the Skin Department: Dr. Sequeira. Consulting Dental Surgeon: Mr. Barrett. Consulting Anæsthetist: Dr. Hewitt. Ophthalmic Surgeons: Mr. A. B. Roxburgh and Mr. Lister. Surgeon to the Throat Department: Dr. Lambert Lack. Aural Surgeon: Mr. Hunter Tod. Medical Officer in charge of the Electrical Department: Dr E. R. Morton. Physician in charge of the Photo-therapy Department: Dr. Sequeira. Analyst to the Hospital: Mr. Hugh Candy. Bacteriologist to the Hospital: Dr. W. Bulloch. Dental Surgeons: Mr. Dolamore and Mr. Farmer. Anæsthetists: Dr. Probyn-Williams, Mr. Hilliard, and Mr. Clapham.

Lecturers.—Medicine: Dr. Percy Kidd and Dr. Hadley. Clinical Medicine: the Physicians and Assistant Physicians. Surgery: Mr. C. W. Mansell-Moullin. Clinical Surgery: the Surgeons and Assistant Surgeons. Anatomy: Dr. A. Keith. Physiology: Dr. Leonard Hill, Dr. Grünbaum, and Mr. Greenwood. Chemistry: Mr. F. J. M. Page and Mr. Hugh Candy. Pathology—(1) Medical: Dr. Schorstein; (2) General and (3) Surgical: Dr. W. Bulloch. Midwifery and Diseases of Women: Dr. Lewers. Clinical Obstetrics: The Obstetric Physicians. Practical Obstetrics: Dr. Andrews. Forensic Medicine—(1) Public Health: Dr. J. C. Thresh; and (2) Medical Jurisprudence and Toxicology: Dr. F. J. Smith. Public Health and Sanitary Science: Dr. W. Bulloch, Dr. John C. Thresh, and Mr. F. J. M. Page. Mental Diseases: Dr. J. Kennedy Will. Materia Medica and General Therapeutics: Dr. Francis Warner and Dr. Grünbaum. Biology: Mr. G. P. Mudge. Experimental Physics: Mr. F. J. M. Page, Mr. Hugh Candy, and Mr. Griffith. Ophthalmic Surgery: Mr. A. B. Roxburgh. Diseases of the Throat: Dr. Lambert Lack. Aural Surgery: Mr. Hunter Tod. Anatomy and Pathology of the Teeth: Mr. H. Dolamore and Mr. F. M. Farmer. Practical Anatomy: Dr. Arthur Keith, Mr. Howard, and Mr. Patterson. Practical Physiology and Histology: Dr. Leonard Hill, Dr. Grünbaum, and Mr. Greenwood. Foods and Dietetics: Dr. R. Hutchison. Practical Chemistry: Mr. F. J. M. Page and Mr. Hugh Candy. Operative Surgery: Mr. H. P. Dean. Demonstrators of Morbid Anatomy: Dr. F. J. Smith, Dr. W. J. H. Hadley, Dr. Dawson, and Dr. Lewis Smith. Bacteriology: Dr. W. Bulloch and Mr. Twort. Pathological Histology: Dr. W. Bulloch. Inoculation Department: Dr. Western. Therapeutic Electricity and Radiography: Dr. A. E. Morton. Anæsthetics: Dr. R. J. Probyn-Williams. Elementary Clinical Medicine: Dr. Robert Hutchison and Dr. Lewis Smith. Medical Tutor: Dr. Wall. Elemental Clinical Surgery: Mr. H. M. Rigby and Mr. J. Sherren. Surgical Tutor: Mr. Sherren. Obstetric Tutor: Dr. H. R. Andrews. As Emeritus Professor of Surgery Mr. Hutchinson will give in the Summer Session, and Sir Frederick Treves, Bart., will give in the Winter

Consulting Obstetric Physician: Dr. Barnes. Consulting Ophthalmic Surgeon: Mr. Brudenell Carter. Consulting Aural Surgeon: Sir William Dalby. Consulting Dental Surgeon: Mr. Winterbottom. Physicians: Dr. William Ewart, Dr. H. D. Rolleston. Dr. Ogle, and Dr. Latham. Obstetric Physician: Dr. W. R. Dakin. Assistant Physicians: Dr. Collier, Dr. Spriggs, and Dr. Jex-Blake. Assistant Obstetric Physician: Dr. A. F. Stabb. Physician to the Skin Department: Dr. Wyndham Cottle. Physician Anæsthetist: Dr. F. Hewitt. Surgeons: Mr. C. T. Dent, Mr. G. R. Turner, Mr. A. M. Sheild, and Mr. F. Jaffrey. Ophthalmic Surgeon: Mr. H. B. Grimsdale. Assistant Surgeons: Mr. H. S. Pendlebury, Mr. T. Crisp English, and Mr. L. Jones. Surgeon to the Orthopædic Department: Mr. F. Jaffrey. Surgeon to the Throat Department: Mr. H. S. Barwell. Aural Surgeon: Mr. W. C. Bull. Dental Surgeon: Mr. N. G. Bennett. Assistant Dental Surgeon: Mr. Morley.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 602 beds.

House physicians, house surgeons, assistant house physicians and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical and medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical council according to merit and without extra payment. The house physicians, of whom there are four, hold office for six months each. The assistant house physicians, who hold office for three months, attend in the out-patient department five afternoons in the week and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons and there are four out-patient officers appointed each three months. The surgeons' dressers are selected from those students who have completed their third winter session and have been most diligent in the junior appointments. They hold office for three or six months. Six are attached to each surgeon and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, four in number, are provided with board and lodging in the college free of expense. The college stands upon a site fronting the east gate of the hospital and is connected with it by a subway. The building serves as a Residential College for Students and at the same time provides accommodation for the Students' Club.

Medical and Surgical Staff.—Consulting Physicians: Sir Samuel Wilks, Bart., Dr. F. W. Pavy, Dr. P. H. Pye-Smith, and Dr. J. F. Goodhart. Consulting Surgeons: Mr. Thomas Bryant, Sir H. G. Howse, and Mr. Jacobson. Consulting Obstetric Physician: Dr. A. L. Galabin. Consulting Physician for Mental Diseases: Dr. G. H. Savage. Consulting Aural Surgeon: Mr. W. Laidlaw Purves. Consulting Anæsthetist: Mr. Tom Bird. Physicians and Assistant Physicians: Dr. Frederick Taylor, Dr. W. Hale White, Dr. G. Newton Pitt, Sir Cooper Perry, Dr. L. E. Shaw, Dr. J. Fawcett, Dr. A. P. Beddard, and Dr. H. S French. Surgeons and Assistant Surgeons: Mr. C. H. Golding-Bird, Mr. Charters J. Symonds, Mr. W. Arbuthnot Lane, Mr. L. A. Dunn, Sir Alfred Fripp, C.B., C.V.O., Mr. F. J. Steward, Mr. Fagge, and Mr. R. P. Rowlands. Obstetric Physicians: Dr. P. Horrocks and Mr. J. H. Targett. Assistant Obstetric Physician: Mr. G. Bellingham Smith. Ophthalmic Surgeons: Mr. H. L. Eason and Mr. A. W. Ormond. Physician in Charge of Skin Department: Sir Cooper Perry. Physician for Mental Diseases: Dr. M. Craig. Surgeon in Charge of Throat Department: Mr. F. J. Steward. Surgeon in Charge of Aural Department: Mr. C. H. Fagge. Dental Surgeons: Mr. F. Newland-Pedley, Mr. W. A. Maggs, and Mr. R. Wynne Rouw. Anæsthetists: Mr. G. Rowell, Dr. H. F. Lancaster, Mr. C. J. Ogle, Mr. P. Turner, Mr. H. T. Hicks, Dr. D. Forsyth, Mr. W. M. Mollison, and Mr. A. R. Thompson. Medical Registrars and Tutors: Dr. H. F. Bell Walker and Mr. H. O. C. Mann. Obstetric Registrar and Tutor: Mr. H. T. Hicks. Surgical Registrar and Tutor: Mr. R. A. Greeves. Actino-Therapeutic Department: Mr. G. T. S. Sichel. Radiographer: Mr. E. W. H. Shenton. Bacteriologist to the Hospital: Dr. W. H. Eyre. Resident Surgical Officer: Mr. E. C. Hughes, M.B., B.C. Hon. Librarian, Wills Library: Dr. L. E. Shaw. Lying-in Charity: Mr. Targett and Mr. Bellingham Smith. Dean of the Medical School: Dr. H. L. Eason. Warden of the College: W. M. Mollison, M.C.

Lecturers and Demonstrators.—Clinical Medicine: the Physicians and Assistant Physicians. Clinical Surgery: the Surgeons and Assistant Surgeons. Medicine: Dr. Taylor and Dr. Hale White. Practical Medicine: Dr. Bell Walker and Mr. Mann. Surgery: Mr. Golding-Bird, Mr. Symonds, Mr. Lane, and Mr. Dunn. Operative Surgery: Sir Alfred Fripp and Mr. Steward. Practical Surgery: Mr. Greeves. Midwifery and Diseases of Women: Dr. Horrocks and Mr. Targett. Practical Obstetrics: Mr. Hicks. Mental Diseases: Dr. Craig. Ophthalmic Surgery: Mr. Eason. Dental Surgery: Mr. Wynne Rouw. Aural Surgery: Mr. Fagge. Diseases of the Skin: Sir Cooper Perry. Diseases of the Throat: Mr. Steward. Anæsthetics: Mr. Rowell. Hygiene and Public Health: Dr. Sykes. Pathology: Dr. Pitt. Gordon Lecturer on Experimental Pathology: Dr. F. A. Bainbridge. Morbid Anatomy: Dr. Fawcett and Dr. French. Morbid Histology and Bacteriology: Mr. Bellingham Smith and Dr. Eyre. Medical and Surgical Pathology Classes: Dr. Fawcett and Mr. Steward. Bacteriology: Dr. Eyre. Practical Bacteriology: Dr. Eyre. Forensic Medicine: Sir Thomas Stevenson, M.D. Anatomy: Sir Alfred Fripp and Mr. Steward. Practical Anatomy: Mr. P. Turner, Mr. W. M. Mollison, and Mr. A. R. Thompson, M.B, Ch.B. Physiology: Dr. Pembrey. Practical Physiology: Dr. Pembrey, Mr. A. F. Hertz, M.B, B Ch., and Mr. H. C. Cameron, M B., B.C. Materia Medica and Therapeutics: Dr. A. P. Beddard. Practical Pharmacy: the Hospital Pharmacist. Chemistry: Dr. Wade. Practical Chemistry: Dr. Wade, Mr. Ball, and Mr. Merriman. Experimental Physics: Dr. Fison and Mr. Merriman. Biology: Mr. Assheton, Dr. Stevens, and Mr. Thompson. Psychology: Dr. Craig.

KING'S COLLEGE.—The Faculty of Medicine at King's College is now divided into two parts; the first is concerned with Preliminary and Intermediate subjects and instruction on these is given in the College laboratories. This department is now designated Faculty of Science (Medical division); the second deals with the Advanced or Final subjects of the curriculum, instruction on which is given at the hospital, except in subjects like Bacteriology where laboratory courses are necessary.

Lecturers on Preliminary and Intermediate Subjects.—Anatomy: Dr. P. Thompson (Professor) and Dr. C. J. Jenkins (Lecturer). Physiology: Dr. W. D. Halliburton (Professor), Dr. H. W. Lyle (Lecturer), Dr. O. Rosenheim (Lecturer on Chemical Physiology), and Dr. C. S. Myers (Lecturer on Experimental Psychology). Zoology: Dr. A. Dendy (Professor). Botany: Dr. W. B. Bottomley (Professor) and Mr. E. J. Schwartz (Demonstrator). Chemistry: Dr. J. M. Thomson (Professor), Mr. H. Jackson (Assistant Professor), and Mr. P. H. Kirkaldy (Lecturer). Physics: Dr. Wilson. Materia Medica and Pharmacology: Dr. W. E. Dixon (Professor).

Fees.—For London University Course: for Preliminary Scientific (Part I.), 25 guineas; for Preliminary Scientific (Part II.) and Intermediate M.E., 55 guineas, or two instalments of 30 guineas each. For Conjoint Board Course; for First examination, 20 guineas; for Second examination, 55 guineas, or two instalments of 30 guineas each. For prospectus and further information application should be made to Dr. P. Thompson, Dean of the department.

King's College Hospital contains 217 available beds. Resident medical officers have rooms at the hospital and commons free; they are selected by examination and hold their appointment for six months or a year. There are two house physicians, two physician accoucheur assistants, and three house surgeons. Sambrooke registrarships, value £50 per annum, are tenable for two years. There are also senior medical and surgical, and obstetric registrars and in Surgery: The Surgeons. Clinical Lectures on Diseases of the Ear, Throat, and Nose: Mr. S. Paget. Lectures in Ophthalmology: Mr. Lang. Lectures in Dental Surgery: Mr. Hern. Public Health and Bacteriology: Mr. Foulerton. Summer Session: Pharmacology and Therapeutics: Dr. R. A. Young. Midwifery: Dr. Comyns Berkeley. Pathological Histology: Dr. Voelcker. Practical Toxicology: Dr. Kellas. Tropical Medicine: Dr. Crombie. Mental Diseases: Dr. Mickle. Lectures in Dermatology: Dr. Pringle. Anatomy, Chemistry, and Physiology: as in Winter Session. Tutors—Medicine: Dr. Campbell Thomson; Surgery: Mr. Kellock; Obstetrics: Dr. Victor Bonney; Practical Pharmacy: Mr. Fardon.

ST. THOMAS'S HOSPITAL.—The annual composition fee is 30 guineas—in addition to a fee on entrance. Qualified practitioners are admitted by a joint ticket to the practice of 15 hospitals on terms which may be ascertained from the medical secretary.

Staff.—Consulting Physicians: Dr. Harley and Dr. Payne. Consulting Surgeon: Mr. S. Jones. Consulting Obstetrical Physicians: Dr. Gervis and Dr. Cullingworth. Consulting Ophthalmic Surgeons: Mr. Liebreich and Mr. Nettleship. Consulting Anæsthetist: Mr. W. Tyrrell. Physicians: Dr. Sharkey, Dr. Acland, Dr. Hawkins, and Dr. Mackenzie. Surgeons: Mr. Clutton, Mr. Pitts, Mr. G. H. Makins, C.B., Mr. Battle, and Mr. Ballance. Physicians to Out-patients: Dr. Turney, Dr. Perkins, Dr. Colman, and Dr. Box. Surgeons to Out-patients: Mr. H. B. Robinson, Mr. C. S. Wallace, and Mr. E. M. Corner. Obstetrical Physician: Dr. Tate. Obstetrical Physician to Out-patients: Dr. Fairbairn. Ophthalmic Surgeon: Mr. Lawford. Ophthalmic Surgeon to Out-patients: Mr. Fisher (Dean of the school). Physician for Diseases of Children: Dr. Box. Surgeon for Diseases of Children: Mr. P. W. G. Sargent. Surgeon for Diseases of the Throat: Mr. H. B. Robinson. Physician for Diseases of the Skin: Dr. E. Stainer. Surgeon for Diseases of the Ear: Mr. Ballance, with Mr. Marriage in charge of Out-patients. Physician, Electrical Department: Dr. Turney. Dental Surgeons: Mr. J. G. Turner and Mr. G. L. Bates. Resident Assistant Physician: Dr. Harwood-Yarred. Resident Assistant Surgeon: Mr. C. A. R. Nitch. Anæsthetists: Mr. H Low, Dr. Bevan, Mr. Mennell, and Dr. Hedley. Pharmaceutist: Mr. H. Wilson. Curator of Museum: Mr. S. G. Shattock. Superintendent of Clinical Laboratory: Mr. Dudgeon. Superintendent of X-ray Department: Dr. Greg.

Lecturers: Winter Session.—Practical Anatomy Demonstrators: Mr. F. G. Parsons and Mr. P. W. G. Sargent. Descriptive and Surgical Anatomy: Mr. F. G. Parsons. Chemistry and Physical Chemistry: Dr. Le Sueur. Physiology and General Anatomy: Dr. J. B. Leathes. Biology: Mr. T. G. Hill. Pathology and Bacteriology: Dr. Turney, Mr. Shattock, and Mr. Dudgeon. Surgery: Mr. Makins and Mr. Ballance. Theory and Practice of Medicine: Dr. Sharkey and Dr. Hawkins. Practical and Manipulative Surgery: Mr. Robinson and Mr. Wallace. Comparative Anatomy: Mr. Parsons. Applied Anatomy: Dr. Box. Anæsthetics: Mr. Tyrrell and Dr. Low. Physics and Natural Philosophy: Dr. Le Sueur. Clinical Medicine: The Physicians. Surgery: The Surgeons. Clinical Midwifery and Diseases of Women: Dr. Tate. Diseases of the Eye: Mr. Lawford. Pharmacology and Therapeutics: Dr. Perkins. Clinical Lectures on Throat Disease: Mr. H. B. Robinson. Physiological Demonstrator: Mr J. F. Cunningham. Obstetrical Demonstrators: Dr. Fairbairn and Dr. Bell. Elementary Clinical Medicine: Dr. Perkins, Dr. Colman, and Dr. Box. Surgical Classes: Mr. Wallace, Mr. Corner, Mr. Fisher, and Mr. Shattock.

Summer Session.—Anatomical Demonstrators: Mr. F. G. Parsons and Mr. P. W. G. Sargent. Biology: Mr. T. G. Hill. Forensic Medicine and Toxicology: Dr. Colman. Midwifery: Dr. Tate. Botany: Mr. Hill. Chemistry and Practical Chemistry: Dr. Le Sueur. Mental Diseases: Dr. R. Percy Smith. Public Health: Dr. E. Seaton. Practical and Manipulative Surgery: Mr. Robinson and Mr. Wallace. Practical Physiology: Dr. J. B. Leathes. Diseases of the Eye: Mr. Lawford. Pathology and Bacteriology: Dr. Turney, Mr. Shattock, and Mr Dudgeon. Operative Surgery: Mr. Battle, Mr. Robinson, and Mr. Wallace. Lectures on Clinical Medicine and Surgery are delivered every Wednesday and Thursday. Special Departments for the Diseases of Women and Children, and for Diseases of the Eye, Skin, Throat, and Ear. Instruction in Electro-Therapeutics by Dr. Turney. Instruction in Dental Surgery by Mr. J. G. Turner and Mr. G. L. Bates. Instruction in Vaccination by Dr. Cope.

UNIVERSITY COLLEGE, LONDON.—*Faculty of Medical Sciences.*—Provost: T. Gregory Foster, Ph.D. Dean: Professor G. D. Thane. Vice-Dean: Professor F. T. Trouton.

Composition fees.—For the courses required by the University of London. 1. For the Preliminary Scientific Course, 25 guineas, entitling to one attendance. 2. For the Intermediate Course, 55 guineas if paid in one sum; 60 guineas if paid in two instalments of £30 guineas each. This fee entitles to attendance on Anatomy and Physiology during three years and to one attendance on Organic Chemistry, Pharmacology, and Materia Medica.

For the medical education required by the Examining Board in England and the Society of Apothecaries. First examination, Parts I., II., III., 20 guineas, entitling to one attendance; first examination, Part IV., and second examination, 55 guineas if paid in one sum, and 60 guineas if paid in two instalments of 30 guineas each. This fee entitles to attendance during three years.

Professors and Lecturers.—1. Preliminary Scientific Course.—Chemistry: Professor Sir William Ramsay, K.C.B., F.R.S.; assistants, Professor E. C. C. Baly, F.I.C., J. K. H. Inglis, D.Sc., M.A., N. T. M. Wilsmore, M.Sc., Samuel Smiles, D.Sc.; demonstrators, E. Foxwell, W. H. Gibson, T. P. Hilditch, H. E. Watson. Physics: Professor F. T. Trouton, M.A., F.R.S.; assistants, Professor A. W. Porter, B.Sc., N. Eumorfopoulos, B.Sc., A. O. Rankine, B.Sc. Botany: Professor F. W. Oliver, M.A., D.Sc., F.R.S.; assistant professors, A. G. Tansley, M.A., F. E. Fritsch, D.Sc., Ph.D. Zoology: Professor J. P. Hill, D.Sc.; assistant professor, G. C. Chubb, D.Sc. 2. Intermediate Course.—Anatomy: Professor G. D. Thane, LL.D.; demonstrators, W. B. L. Trotter, M.S., F.R.C.S., G. E. Waugh, B.S., F.R.C.S.; assistant demonstrators, W. Appleyard, M.B., B.S., H. T. Mant, M.B., B.S. Physiology: Professor E. H. Starling, M.D., B.S., F.R.C.P., F.R.S.; assistant professors, W. M. Bayliss, M.A., D.Sc., F.R.S., G. A. Buckmaster, M.A., M.D., D.P.H.; assistants, R. H. Aders-Plimmer, D.Sc., J. M. Hamill, M.A., M.B., B.C. Cantab., B.Sc. Lond. Lecturers: J. H. Parsons, M.B., D.Sc., F.R.C.S., W. Page May, M.D., D.Sc., F.R.C.S., S. B. Schryver, D.Sc. Pharmacology: Professor A. R. Cushny. Organic Chemistry: Professor J. Norman Collie.

University College Hospital Medical School.—Dean: Professor Sidney Martin, M.D., F.R.C.P., F.R.S. Vice-Dean: H. Batty Shaw, M.D., F.R.C.P. Fees for Preliminary and Intermediate Course: See under University College, above. For the Final M.B., B.S. Course, 80 guineas if paid in one sum, 82 guineas if paid in two instalments, as follows—first year, 50 guineas; second year, 32 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. Students who obtain a medical qualification within three years of the time of commencing this course are not required to pay an additional fee for further attendance. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham.

For the medical education required by the Examining Board in England and the Society of Apothecaries. For the Course required for the third examination, 80 guineas if paid in one sum and 82 guineas if paid in two instalments, as follows—first year, 50 guineas; second year, 32 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Pharmacy, Vaccination, and attendance at a Fever Hospital are not included. Students who obtain a medical qualification within three years of the time of commencing this course are not required to pay an additional fee for further attendance. The composition fee for the courses required for the L.D.S. is 65 guineas, or exclusive of Chemistry, Practical Chemistry, Physics, and Materia Medica 50 guineas.

Eight house physicians, eight house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric

Session a course of lectures in Clinical Surgery. The special subjects and the dates will be announced in due course. Dr. Hewitt, as Emeritus Lecturer on Anæsthetics, will give a course of lectures during the first half of the Winter Session. Warden: Mr. Munro Scott.

ST. MARY'S HOSPITAL.—The hospital contains 281 beds. The situation of the hospital in the centre of the residential districts of Paddington, Bayswater, and North Kensington renders it especially convenient to students who wish to reside in the immediate vicinity, and a register of approved lodgings is kept in the office or the Medical School. All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anæsthetists are appointed in each year and receive board and residence in the hospital. Entrance scholarships in Natural Science, one of £145, one of £78 15*s.*, two of £52 10*s.*, and two of £63 (for University students), are awarded annually by examination in September.

Enlargement of the Hospital.—With the opening of the Clarence Wing the number of beds will be raised to 350, and additional operating theatres, a clinical theatre, and a clinical laboratory will be provided.

During the past year a department for Therapeutic Inoculation has been instituted under Sir Almroth Wright, F.R.S., the work being carried on in two special laboratories in the Museum Buildings.

Special Tuition.—In addition to systematic courses of lectures and demonstrations special tuition is provided for the Intermediate and Final Examinations of the Universities of Oxford, Cambridge, and London, and for the Primary and Final F.R.C.S.

Preliminary Scientific Course.—Special classes, including lectures and laboratory work, are held throughout the year under recognised teachers of the University of London.

The composition fee for full students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in Anatomy and Physiology are admitted on payment of a composition fee of 60 guineas (£63) paid in one sum or by payment of two annual instalments of 35 guineas (£36 15*s.*) and 30 guineas (£31 10*s.*) respectively. University students who have not completed their examination in Anatomy and Physiology pay an annual fee of 25 guineas (£26 5*s.*) until they have passed these examinations, and then pay the composition fee. Separate courses of lectures, laboratory work, or hospital practice may be taken. The School Calendar and full information can be obtained from the Secretary, St. Mary's Hospital Medical School, Paddington, W.

Staff.—Consulting Physicians: Sir William Broadbent and Dr. Cheadle. Consulting Surgeons: Mr. A. T. Norton, Mr. Edmund Owen, Mr. Herbert Page, Mr. G. P. Field (Aural), Mr. Howard-Hayward (Dental), Sir G. Anderson Critchett (Ophthalmic), and Mr. Malcolm Morris (Skin). Physicians: Dr. D. B. Lees, Dr. Sidney Phillips, and Dr. A. P. Luff. Surgeons: Mr. A. J. Pepper, Mr. J. Ernest Lane, and Mr. H. Stansfield Collier. Physicians in charge of Out-Patients: Dr. H. A. Caley, Dr. Wilfred Harris, and Dr. John Broadbent. Surgeons in Charge of Out-Patients: Mr. V. Warren Low, Mr. W. H. Clayton-Greene, and Mr. Maynard Smith. Physician-Accoucheur: Dr. Montagu Handfield-Jones. Physician-Accoucheur in charge of Out-Patients: Dr. W. J. Gow. Physician in charge of Children's Department: Dr. Sidney Phillips. Ophthalmic Surgeon: Mr. H. E. Juler. Assistant Ophthalmic Surgeon: Mr. Leslie Paton. Physician to the Skin Department: Dr. Graham Little. Dental Surgeon: Mr. Morton Smale. Aural Surgeon: Dr. G. William Hill. Surgeon to the Throat Department: Dr. Scanes Spicer. Administrators of Anæsthetics: Mr. Henry Davis, Mr. Blumfeld, and Mr. Collum. Director in Medical Charge of Inoculation Department: Sir A. E. Wright. Dean: Dr. H. A. Caley.

Lecturers.—Clinical Medicine: Dr. D. B. Lees. Clinical Surgery: Mr. A. J. Pepper. Medicine: Dr. Sidney Phillips. Surgery: Mr. J. Ernest Lane and Mr. H. Stansfield Collier. Practical and Operative Surgery: Mr. H. Stansfield Collier and Mr. V. W. Low. Pathology: Sir A. E. Wright. Bacteriology: Sir A. E. Wright. Pathological Chemistry: Dr. W. H. Willcox. Midwifery and Gynæcology: Dr. M. Handfield-Jones. Materia Medica and Therapeutics: Dr. H. A. Caley. Forensic Medicine: Dr. A. P. Luff and Dr. Willcox. Descriptive and Surgical Anatomy: Mr. W. H. Clayton-Greene. Physiology and Histology: Dr. N. H. Alcock. Demonstrator: Dr. B. J. Collingwood. Biology: Dr. W. G. Ridewood. Demonstrator: Mr. H. B. Fantham. Chemistry: Dr. G. Senter. Physics: Mr. W. H. White. Hygiene and Public Health: Dr. W. H. Willcox. Mental Diseases: Dr. Theo. B. Hyslop. Diseases of the Eye: Mr. Leslie Paton. Diseases of the Ear: Dr. G. William Hill. Diseases of the Skin: Dr. Graham Little. Diseases of the Throat: Dr. Scanes Spicer. Dental Surgery: Mr. Morton Smale. Medical Tutor: Dr. W. J. Harris. Surgical Tutor: Mr. V. Warren Low. Obstetric Tutor: Dr. T. G. Stevens. Medical Registrar: Dr. F. S. Langmead. Surgical Registrar: Mr. C. I. Graham. Electrical Department: Dr. W. J. Harris. Curator of the Museum: Dr. B. H. Spilsbury. Anatomy: Mr. W. Ashdowne (senior demonstrator). Practical Pharmacy: Mr. E. A. Andrews (demonstrator). School Secretary: Mr. B. E. Matthews.

MIDDLESEX HOSPITAL.—The hospital contains 340 beds. There is a special wing for patients suffering from cancer, consisting of four wards, containing 40 beds; here cancer patients are received and attended for a period limited only by the duration of their disease.

Hospital Appointments.—All hospital appointments are allotted to students without any extra fee. Eighteen Resident Appointments are annually filled from the pupils of the hospital, each appointment extending over six months.

Special Classes are held to prepare students for the Inter. M.B. (Lond.) Examination and for the Primary Examination for the diploma of F.R.C.S. Eng.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects included in the examinations in Medicine and Surgery in the United Kingdom and for the diploma in Public Health; and ample laboratory and class-room accommodation is provided for the teaching of the various subjects of the curriculum and for original research in Medicine, Pathology, or Bacteriology.

A Residential College to accommodate a limited number of students adjoins the hospital. Breakfast, luncheon, and dinner are supplied in the College Hall at a very moderate charge.

Fees.—The Composition Fee for the entire curriculum is 135 guineas, or 145 guineas if paid in three instalments. The fee for London University students is 145 guineas; for those who have passed the Preliminary Scientific 120 guineas. The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments. Students who have completed the study of Anatomy and Physiology or passed the London Preliminary Scientific M.B. Examination are received on special terms.

Staff.—Consulting Physicians: Dr. W. Cayley, Dr. Sydney Coupland, and Sir Richard Douglas Powell. Physicians: Dr. J. K. Fowler, Dr. W. Pasteur, and Dr. W. E. Wynter. Obstetric Physician: Dr. W. Duncan. Physician to Out-patients. Dr. A. F. Voelcker. Assistant Physicians: Dr. F. J. Wethered, Dr. H. Campbell Thompson, and Dr. R. A. Young. Consulting Physician to the Skin Department: Dr. J. J. R. Liveing. Physician to the Skin Department: Dr. Comyns Pringle. Assistant Obstetric Physician: Dr. Comyns Berkeley. Consulting Surgeons: Mr. Nunn and Mr. Morris. Surgeons: Mr. Clark, Mr. Gould, and Mr. Bland-Sutton. Surgeons to Out-patients: Mr. Murray (Dean of the school) and Mr. Kellock. Assistant Surgeon: Mr. Handley. Ophthalmic Surgeon: Mr. W. Lang. Aural Surgeon: Mr. S. Paget. Dental Surgeon: Mr. W. Hern. Assistant Dental Surgeon: Mr. Nowell. Curator of the Museum and Pathologist: Dr. Lakin. Registrars: Dr. O. K. Williamson, Mr. Hastings, and Dr. Victor Bonney. Resident Medical Officer: Mr. E. A. Fardon. Chloroformists: Mr. Norton, Mr. T. G. A. Burns, and Mr. H. P. Noble.

Lecturers.—Winter Session: Anatomy: Dr. Wright. Demonstrator: Dr. Gladstone. Biology and Physiology: Mr. Goodall. Demonstrator: Mr. Earle. Chemistry: Dr. Kellas. Medicine: Dr. Pasteur and Dr. Wynter. Practical Medicine: Dr. Voelcker. Emeritus Lecturer in Surgery: Mr. Henry Morris. Surgery: Mr. Clark, Mr. Pearce Gould, and Mr. Bland-Sutton. Practical Surgery: Mr. Murray. Operative Surgery: Mr. Murray. Practical Midwifery: Dr. Bonney. Pathology: Dr. Voelcker. Forensic Medicine and Toxicology: Dr. Wethered. Clinical Lectures in Medicine: The Physicians. Clinical Lectures instruction in Anatomy, Physiology, and Practical Pharmacology are provided for students preparing for the Intermediate M.B. Examination of the University of London. The rebuilding of the School is now completed and the new buildings afford every facility for efficiency of teaching and of practical work in all departments.

Staff.—Consulting Physicians: Dr. S. West and Dr. T. Crawfurd Hayes. Physicians: Dr. Harrington Sainsbury, Dr. J. W. Carr, and Dr. R. H. P. Crawfurd. Assistant Physicians: Dr. A. G. Phear and Dr. Farquhar Buzzard. Consulting Surgeons: Mr. T. H. Wakley, Mr. W. Rose, and Mr. A. B. Barrow. Surgeons: Mr. J. Berry, Mr. E. W. Roughton, and Mr. W. H. Evans. Assistant Surgeons: Mr. T. Percy Legg and Mr. Cunning. Physician for Diseases of Women: Mrs. Scharlieb, M.S., M.D. Assistant Physician for the Diseases of Women: Miss Vaughan, M.D. Ophthalmic Surgeon: Mr. H. Work Dodd. Surgeon for Diseases of Throat, Nose, and Ear: Mr. E. W. Roughton. Surgeon for Diseases of Skin: Mr. W. H. Evans. Senior Resident Medical Officer: Mr. Atkey. Registrars: Miss Roberts, M.D., B.S., and Miss Ivens, M.S., M.B. Dentist: Mr. F. Todd. Anæsthetists: Mrs. Berry, M.D., B S., and Mrs. Willey, M.S., M.D. Secretary: Mr. C. W. Thies.

Lecturers.—At the school: Anatomy and Practical Anatomy: Mr. Parsons. Physiology and Practical Physiology: Dr. Brodie and Miss Cullis. Chemistry: Miss C. de B. Evans, D.Sc. *Practical Chemistry*: Miss Widdows, B.Sc. Physics: Miss E. Stoney. Biology: Mr. Mudge. Materia Medica: Dr. R. H. P. Crawfurd. Practice of Medicine: Miss Cock, M.D., and Dr. J. W. Carr. Midwifery: Mrs. Scharlieb, M.S. Gynæcology: Mrs. Stanley Boyd. Forensic Medicine: Dr. Hawthorne. Toxicology: Dr. Wilson Hake. Practice of Surgery: Mr. Berry. Operative Surgery: Mr. Roughton. Ophthalmic Surgery: Miss Ellaby. Pathology: Dr. F. W. Andrewes. Mental Pathology: Dr. Mercier. Tropical Diseases: Sir Patrick Manson. Operative Midwifery: Miss McCall, M.D., and Miss Vaughan, M.D. Demonstrator of Practical Gynæcology, Miss Vaughan, M.D.; of Anatomy, Miss Hamilton, M.D., and Miss Seaton-Smith, M.B.; of Chemistry, Miss Laycock, B.Sc.; of Practical Pharmacology, Mrs. Clarke Keer. At the Royal Free Hospital: Clinical Medicine: Dr. Sainsbury and Dr. Carr. Clinical Surgery: Mr. Berry and Mr. Roughton. Clinical Obstetrics: Mrs. Scharlieb, M.S. Pathology: Dr. Phear. Bacteriology: Mr. Roughton. Surgical Tutors: Mr. W. Evans, Mr. Legg, and Mr. Cunning. Medical Tutor: Dr. Crawfurd. Demonstrator of Auscultation: Dr. Phear. Demonstrator of Practical Clinical Medicine: Miss Woodcock, M.D. Practical Pathology: Miss Ivens, M.S.

Dean of the School, Miss Cock, M.D.; Honorary Secretary, Mrs. Thorne; Secretary, Miss Douie, M.B.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

BETHLEM ROYAL HOSPITAL.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six months, commencing July 1st and Jan. 1st, and will be provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. They will be under the direction of the Resident Physician and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital and qualified practitioners may attend for a period of three months on payment of a fee of £3 3*s*. Lectures are also given in connexion with the London Post-graduate Course.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton (318 beds).—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £1 1*s*. for one month; three months, £2 2*s*.; perpetual, £5 5*s*. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The next course will commence in October. Clinical Assistants are appointed to the Assistant Physician in the out-patient department and Clinical Clerks to the Physician in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 318 beds in the two buildings.

Staff.—Consulting Physicians: Dr. J. E. Pollock, Dr. E. S. Thompson, Sir Richard Douglas Powell, Dr. F. T. Roberts, Dr. C. T. Williams, Dr. J. M. Bruce, Dr. T. H. Green, Dr. J. K. Fowler, Dr. T. D. Acland, and Dr. P. Kidd. Physicians: Dr. R. Maguire, Dr. H. W. G. Mackenzie, Dr. S. H. Habershon, Dr. G. Schorstein, and Dr. F. J. Wethered. Assistant Physicians: Dr. P. Horton-Smith Hartley, Dr. J. J. Perkins, Dr. A. Latham, Dr. H. Batty Shaw, Dr. W. C. Bosanquet, and Dr. R. A. Young. Consulting Surgeons: Lord Lister and Mr. R. J. Godlee. Surgeon: Mr. S. Boyd. Dental Surgeon: Mr. G. L. Bates. Resident Medical Officer: Dr. F. C. Shrubsall.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—During the past year 1143 in-patients have been treated in the wards, and the large number of 38,290 cases since the opening of the wards in 1855. The number of out-patients treated during 1905 was 17,124 and 706,787 since the commencement of the institution in 1848. Information as to medical instruction can be obtained on application to Dr. E. Clifford Beale, the Secretary of the Clinical Sub-committee at the hospital.

Staff.—Consulting Physicians: Dr. J. C. Thorowgood, Dr. Eustace Smith, Dr. Vincent D. Harris, Sir William S. Church, Bart., K.C.B., M.D., F.R.C.P., and Dr. E. Clifford Beale. Consulting Surgeon: Lord Lister. Physicians: Dr. G. A. Heron, Dr. Harrington Sainsbury, Dr. T. Glover Lyon, Sir Hugh Beevor, Bart., Dr. W. J. Hadley, Dr. E. H. Colbeck, and Dr. Arnold Chaplin. Surgeon: Mr. J. F. C. H. Macready, F.R.C.S. Physicians to Out-patients: Dr. Hugh Walsham, Dr. Oliver K. Williamson, Dr. Clive-Riviere, Dr. O. F. F. Grünbaum, Dr. R. Fielding-Ould, and Dr. A. I. Simey. Surgeon Dentist: Mr. Evelyn C. Sprawson, M.R.C.S., L.R.C.P. Secretary: Henry T. Dudley Ryder. Secretary of the Medical Committee: Dr. Clive Riviere.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—In addition to the new In-patient Department, and operation theatre the hospital has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 10,052 out-patients (involving over 50,000 attendances) and 354 in-patients were treated. The fee for three months' attendance, 3 guineas; for six months, 5 guineas. The post-graduate teaching consists of successive series of practical demonstrations by the members of the staff delivered once weekly during the winter and summer sessions. They are so arranged that practitioners joining at any part of the course are enabled to complete the group of subjects. The fee for each course is one guinea, or with daily attendance at the out-patient department during the period of the course two guineas. Details of subjects &c., will be afforded by the Dean. Considerable attention is given to scientific work, particularly with regard to Bacteriology of the ear and respiratory passages. Operation days: in-patients, Tuesday and Friday, at 2 P.M.; out-patients, daily at 9 A.M. Consulting Physician: Dr. Arthur Orwin. Consulting Surgeon: Mr. Thomas Nunn. Surgeons: Dr. Dundas Grant, Dr. Percy Jakins, Mr. Chichele Nourse, and Dr. Abercrombie. Assistant Surgeons: Mr. Stuart Low, Dr. Andrew Wylie, and Mr. Atkinson. Pathologist: Dr. Wyatt Wingrave. Bacteriologist: Mr. St. George Reid. Dental Surgeon: Mr. Whishaw Wallis. Anæsthetist: Mr. W. Hotten George. Assistant Anæsthetist: Mr. A. B. Kingsford. Defects of Speech: Mr. William Van Praagh. In addition the following appointments are open to qualified members of the profession:—Three Registrars, tenable for twelve months; and twelve Clinical Assistants, tenable for six months. Secretary: Mr. Richard Kershaw. Dean: Dr. Wyatt Wingrave.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—Clinical Demonstrations on the Diseases of the Throat, Nose, and Ear are given daily at 2 P.M. and on Tuesday and Friday evenings at 6 P.M. Operations are performed almost daily at 9.30 A.M. Individual instruction is given in the examination of cases to students attending the hospital. Fees: one month's attendance, £1 1*s*.; three months, £2 2*s*.; perpetual, £5 5*s*. Detailed information may be obtained from the Hon. Secretary of the Medical Committee.

assistants for three months, receiving free board and lodging.

Several gentlemen connected with the College receive students to reside with them. A register of boarding residences is kept in the office of the College for the convenience of students; the residences are not under the control of the College authorities.

Staff.—Consulting Physicians: Dr. H. C. Bastian, Dr. S. Ringer, Sir W. R. Gowers, Sir J. Williams, Bart., and Dr. F. T. Roberts. Physicians: Sir Thomas Barlow, Bart., Dr. J. Rose Bradford, Dr. Sidney Martin, and Dr. J. Risien Russell. Assistant Physicians: Dr. H. Batty Shaw, Dr. F. J. Poynton, and Dr. C. Bolton. Obstetric Physicians: Dr. H. R. Spencer and Dr. G. F. Blacker. Physician, Skin Department: Dr. H. Radcliffe Crocker. Consulting Surgeon: Mr. John Tweedy (Ophthalmic). Surgeons: Mr. A. E. Barker, Mr. R. J. Godlee, Sir Victor Horsley, Mr. Bilton Pollard, and Mr. Raymond Johnson. Assistant Surgeon: Mr. Rupert Bucknall. Ophthalmic Surgeon: Mr. Percy Flemming. Assistant Ophthalmic Surgeon: Mr. J. H. Parsons. Professor and Lecturer on Public Health: Dr. Henry R. Kenwood. Dental Surgeon: Mr. Sidney Spokes. Assistant Dental Surgeon: Mr. H J. Relph. Anæsthetist: Dr. Dudley Buxton. Assistant Anæsthetists: Dr. H. J. Scharlieb and Mr. A. Beresford Kingsford. Surgical Registrar: Mr. P. M. Heath. Resident Medical Officer: Dr. A. M. H. Gray. Pathologist: Dr. F. H. Thiele. Electrotherapeutist: Mr. E. S. Worrall. Radiographer: Mr. R. H. Cooper. Pharmacist: Mr. R. R. Bennett.

The new buildings for University College Hospital, completed by the generosity of the late Sir Blundell Maple, Bart., are now completed and will be opened by H.R.H. the Duke of Connaught on Tuesday, Nov. 6th, 1906.

The new buildings for the Medical School, now in course of erection through the generosity of Sir Donald Currie, will be ready shortly and will contain accommodation for undergraduate and post-graduate students in all departments of medical study subsequent to the intermediate course.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædics, and for Diseases of Women, and a special ward for children. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

A medical and a surgical registrar, each with a salary of £50, are appointed annually. Two house physicians, three house surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons; also one assistant house physician and one assistant house surgeon with commons only. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students of the hospital.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster school for the teaching of these subjects at King's College. Students, however, join the Westminster Medical School as formerly and the Entrance Scholarships remain as heretofore.

D.P.H.—The course of Laboratory Instruction may now be taken. Physics, Mr. Fox; Chemistry, Dr. Hake; Bacteriology, Dr. Bernstein. Fee: seven guineas for three months, 13 guineas for six months.

Bacteriology.—A course in General Bacteriology is given by Dr. Bernstein. Fee £5 5s.

Staff.—Consulting Medical Staff: Dr. H. B. Donkin and Dr. W. H. Allchin. Consulting Surgical Staff: Mr. Richard Davy, Mr. G. Cowell, and Mr. N. C. Macnamara. Consulting Dental Surgeon: Dr. J. Walker. Medical In-patient Staff: Dr. de Havilland Hall, Dr. W. Murrell, and Dr. R. G. Hebb. Obstetric Physician: Dr. W. Rivers Pollock. Surgical In-patient Staff: Mr. C. Stonham, Mr. W. G. Spencer, and Mr. A. H. Tubby. Medical Out-patient Staff: Dr. A. M. Gossage, Dr. Purves Stewart, Dr. Bertram Abrahams, and Dr. Eric Macnamara. Physician for Diseases of the Skin: Dr. T. Colcott Fox. Assistant Obstetric Physician: Dr. G. H. Drummond Robinson. Surgical Out-patient Staff: Mr. W. Turner, Mr. E. P. Paton, Mr. Arthur Evans, and Mr. Rock Carling. Surgeon in Charge of the Throat Department: Mr. P. R. W. De Santi. Ophthalmic Surgeon: Mr. G. Hartridge. Surgeon in charge of the Orthopædic Department: Mr. A. H. Tubby. Surgeon in charge of the Ear Department: Mr. P. R. W. De Santi. Dental Surgeons: Mr. C. W. Glassington and Mr. E. Gardner. Administrators of Anæsthetics: Dr. N. W. Bourns and Dr. V. B. Orr. Assistant Anæsthetist: Dr. Cecil Hughes. Physician Pathologist: Dr. R. G. Hebb. Assistant Pathologist and Curator of Museum: Dr. J. M. Bernstein. Medical Registrar: Dr. Price. Surgical Registrar: Mr. J. M. G. Swainson. Pharmacist: Mr. A. E. Tanner. Secretary: Mr. S. M. Quennell.

Lecturers.—Clinical Medicine: Dr. Hall, Dr. Murrell, and Dr. Hebb. Clinical Surgery: Mr. Stonham, Mr. Spencer, and Mr. Tubby. Clinical Gynæcology: Dr. Pollock (treasurer of the school). Medicine: Dr. Allchin, Dr. Murrell, Dr. Hebb, Dr. Gossage, Dr. Purves Stewart, Dr. Abrahams, Dr. Macnamara, and Dr. Duncan. Diseases of the Skin: Dr. Colcott Fox. Insanity: Dr. Robert Jones. Surgery: Mr. Spencer. Ophthalmic Surgery: Mr. Hartridge. Surgery of the Throat and Nose: Mr. De Santi. Orthopædic Surgery: Mr. Tubby. Aural Surgery: Mr. De Santi. Dental Surgery: Mr. Glassington. Anæsthetics: Dr. Bourns. Operative Surgery: Mr. Stonham. Surgical Anatomy: Mr. Arthur Evans. Practical Surgery: Mr. Turner and Mr. Rock Carling. Surgical Pathology: Mr. Paton (Dean of the school). Midwifery and Diseases of Women: Dr. Pollock. General Pathology and Morbid Anatomy: Dr. Hebb. Post-mortem Demonstrations: Dr. Hebb. Materia Medica, Therapeutics, and Pharmacology: Dr. Dixon. Demonstrator of Practical Pharmacy: Mr. A. E. Tanner. Forensic Medicine: Mr. Henslowe Wellington. Toxicology: Dr. H. Wilson Hake. Public Health: Dr. S. Monckton Copeman. Bacteriology: Dr. Bernstein. Anatomy: Dr. Thompson and Mr. Jenkins. Demonstrator of Practical Anatomy: Mr. Jenkins. Physiology: Dr. Halliburton. Practical Physiology and Histology: Dr. Halliburton, Dr. Lyle, Dr. Myers, and Dr. Rosenheim. Biology: Dr. Bottomley and Mr. Schwartz. Chemistry and Practical Chemistry: Dr. Thomson, Mr. Jackson, and Mr. Kirkaldy. Physics: Dr. Wilson, Dr. Harrison, and Mr. Allen. Secretary and Librarian: Mr. W. Fryer.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the University of London, after the completion of the Preliminary Scientific year, is £135 in one sum, or £145 in four instalments. The fee for the Preliminary Science classes is £25. The fee for the course for the University of Durham, the Society of Apothecaries, and the Conjoint Colleges of Scotland, including Elementary Science, is £140 in one sum, or £150 in four instalments. This entitles students to attend all necessary lectures and practical classes as well as the medical and surgical practice of the hospital, and to hold clerkships and dresserships in the in-patient and out-patient departments. Students can also attend the in-patient and out-patient practice of the New Hospital for Women. Students after qualification can hold at the Royal Free Hospital the posts of house physician, house surgeon, clinical assistants, anæsthetist and assistant anæsthetists, medical and surgical registrars, medical electrician, and museum curator; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Chemistry, and museum curator. They can also hold posts at the New Hospital for Women, which is officered entirely by medical women.

In addition to the list of Scholarships tabulated in another column three Evans Prizes of £3 3s., £2 2s., and £1 1s. are given in alternate years on the results of the class examination in midwifery, and two Durham Prizes, value £5 and £3, are given in alternate years on the results of the class examination in gynæcology, and a prize of £5 is awarded in alternate years on the results of the class examination in Midwifery and Gynæcology respectively. The Evans Prize for Operative Midwifery, value £5 5s., is awarded yearly. Prizes of £10 each are awarded yearly in Anatomy and Physiology. There is also a small fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help. Honoraria from the Mary Royce Memorial Fund are given to the assistant anæsthetists at the Royal Free Hospital. Prizes and Certificates of Honour are awarded in each class at the end of the session.

Special classes for the Preliminary Scientific examination of the University of London are held and special courses of instruction in Anatomy, Physiology, and Practical Pharmacology are provided for students preparing for the Intermediate M.B. Examination of the University of London. The rebuilding of the School is now completed and the new buildings afford every facility for efficiency of teaching and of practical work in all departments.

Staff.—Consulting Physicians: Dr. S. West and Dr. T. Crawfurd Hayes. Physicians: Dr. Harrington Sainsbury, Dr. J. W. Carr, and Dr. R. H. P. Crawfurd. Assistant Physicians: Dr. A. G. Phear and Dr. Farquhar Buzzard. Consulting Surgeons: Mr. T. H. Wakley, Mr. W. Rose, and Mr. A. B. Barrow. Surgeons: Mr. J. Berry, Mr. E. W. Roughton, and Mr. W. H. Evans. Assistant Surgeons: Mr. T. Percy Legg and Mr. Cunning. Physician for Diseases of Women: Mrs. Scharlieb, M.S., M.D. Assistant Physician for the Diseases of Women: Miss Vaughan, M.D. Ophthalmic Surgeon: Mr. H. Work Dodd. Surgeon for Diseases of Throat, Nose, and Ear: Mr. E. W. Roughton. Surgeon for Diseases of Skin: Mr. W. H. Evans. Senior Resident Medical Officer: Mr. Atkey. Registrars: Miss Roberts, M.D., B.S., and Miss Ivens, M.S., M.B. Dentist: Mr. F. Todd. Anæsthetists: Mrs. Berry, M.D., B S., and Mrs. Willey, M.S., M.D. Secretary: Mr. C. W. Thies.

Lecturers.—At the school: Anatomy and Practical Anatomy: Mr. Parsons. Physiology and Practical Physiology: Dr. Brodie and Miss Cullis. Chemistry: Miss C. de B. Evans, D.Sc. Practical Chemistry: Miss Widdows, B.Sc. Physics: Miss E. Stoney. Biology: Mr. Mudge. Materia Medica: Dr. R. H. P. Crawfurd. Practice of Medicine: Miss Cock, M.D., and Dr. J. W. Carr. Midwifery: Mrs. Scharlieb, M.S. Gynæcology: Mrs. Stanley Boyd. Forensic Medicine: Dr. Hawthorne. Toxicology: Dr. Wilson Hake. Practice of Surgery: Mr. Berry. Operative Surgery: Mr. Roughton. Ophthalmic Surgery: Miss Ellaby. Pathology: Dr. F. W. Andrewes. Mental Pathology: Dr. Mercier. Tropical Diseases: Sir Patrick Manson. Operative Midwifery: Miss McCall, M.D., and Miss Vaughan, M.D. Demonstrator of Practical Gynæcology, Miss Vaughan, M.D.; of Anatomy, Miss Hamilton, M.D., and Miss Seaton-Smith, M.B.; of Chemistry, Miss Laycock, B.Sc.; of Practical Pharmacology, Mrs. Clarke Keer. *At the Royal Free Hospital*: Clinical Medicine: Dr. Sainsbury and Dr. Carr. Clinical Surgery: Mr. Berry and Mr. Roughton. Clinical Obstetrics: Mrs. Scharlieb, M.S. Pathology: Dr. Phear. Bacteriology: Mr. Roughton. Surgical Tutors: Mr. W. Evans, Mr. Legg, and Mr. Cunning. Medical Tutor: Dr. Crawfurd. Demonstrator of Auscultation: Dr. Phear. Demonstrator of Practical Clinical Medicine: Miss Woodcock, M.D. Practical Pathology: Miss Ivens, M.S.

Dean of the School, Miss Cock, M.D.; *Honorary* Secretary, Mrs. Thorne; Secretary, Miss Donie, M.B.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

BETHLEM ROYAL HOSPITAL.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six *months*, commencing July 1st and Jan. 1st, and will be provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. They will be under the direction of the Resident Physician and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital and qualified practitioners may attend for a period of three months on payment of a fee of £3 3s. Lectures are also given in connexion with the London Post-graduate Course.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton (318 beds).—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £1 1s. for one month; three months, £2 2s.; perpetual, £5 5s. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The next course will commence in October. Clinical Assistants are appointed to the Assistant Physician in the out-patient department and Clinical Clerks to the Physician in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 318 beds in the two buildings.

Staff.—Consulting Physicians: Dr. J. E. Pollock, Dr. E. S. Thompson, Sir Richard Douglas Powell, Dr. F. T. Roberts, Dr. C. T. Williams, Dr. J. M. Bruce, Dr. T. H. Green, Dr. J. K. Fowler, Dr. T. D. Acland, and Dr. P. Kidd. Physicians: Dr. R. Maguire, Dr. H. W. G. Mackenzie, Dr. S. H. Habershon, Dr. G. Schorstein, and Dr. F. J. Wethered. Assistant Physicians: Dr. P. Horton-Smith Hartley, Dr. J. J. Perkins, Dr. A. Latham, Dr. H. Batty Shaw, Dr. W. C. Bosanquet, and Dr. R. A. Young. Consulting Surgeons: Lord Lister and Mr. R. J. Godlee. Surgeon: Mr. S. Boyd. Dental Surgeon: Mr. G. L. Bates. Resident Medical Officer: Dr. F. C. Shrubsall.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—During the past year 1143 in-patients have been treated in the wards, and the large number of 38,290 cases since the opening of the wards in 1855. The number of out-patients treated during 1905 was 17,134 and 706,787 since the commencement of the institution in 1848. Information as to medical instruction can be obtained on application to Dr. E. Clifford Beale, the Secretary of the Clinical Sub-committee at the hospital.

Staff.—Consulting Physicians: Dr. J. C. Thorowgood, Dr. Eustace Smith, Dr. Vincent D. Harris, Sir William S. Church, Bart., K.C.B., M.D., F.R.C.P., and Dr. E. Clifford Beale. Consulting Surgeon: Lord Lister. Physicians: Dr. G. A. Heron, Dr. Harrington Sainsbury, Dr. T. Glover Lyon, Sir Hugh Beevor, Bart., Dr. W. J. Hadley, Dr. E. H. Colbeck, and Dr. Arnold Chaplin. Surgeon: Mr. J. F. C. H. Macready, F.R.C.S. Physicians to Out-patients: Dr. Hugh Walsham, Dr. Oliver K. Williamson, Dr. Clive Riviere, Dr. O. F. F. Grünbaum, Dr. R. Fielding-Ould, and Dr. A. I. Simey. Surgeon Dentist: Mr. Evelyn C. Sprawson, M.R.C.S, L.R.C.P. Secretary: Henry T. Dudley Ryder. Secretary of the Medical Committee: Dr. Clive Riviere.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—In addition to the new In-patient Department, and operation theatre the hospital has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 10,052 out-patients (involving over 50,000 attendances) and 354 in-patients were treated. The fee for three months' attendance, 3 guineas; for six months, 5 guineas. The post-graduate teaching consists of successive series of practical demonstrations by the members of the staff delivered once weekly during the winter and summer sessions. They are so arranged that practitioners joining at any part of the course are enabled to complete the group of subjects. The fee for each *course* is one guinea, or with daily attendance at the out-patient department during the period of the course two guineas. Details of subjects &c., will be afforded by the Dean. Considerable attention is given to scientific work, particularly with regard to Bacteriology of the ear and respiratory passages. Operation days: in-patients, Tuesday and Friday, at 2 P.M.; out-patients, daily at 9 A.M. Consulting *Physician*: Dr. Arthur Orwin. Consulting Surgeon: Mr. Thomas Nunn. Surgeons: Dr. Dundas Grant, Dr. Percy Jakins, Mr. Chichele Nourse, and Dr. Abercrombie. Assistant Surgeons: Mr. Stuart Low, Dr. Andrew Wylie, and Mr. Atkinson. Pathologist: Dr. Wyatt Wingrave. Bacteriologist: Mr. St. George Reid. Dental Surgeon: Mr. Whishaw Wallis. Anæsthetist: Mr. W. Hotten George. Assistant Anæsthetist: Mr. A. B. Kingsford. Defects of Speech: Mr. William Van Praagh. In addition the following appointments are open to qualified members of the profession:—Three Registrars, tenable for twelve months; and twelve Clinical Assistants, tenable for six months. Secretary: Mr. Richard Kershaw. Dean: Dr. Wyatt Wingrave.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—Clinical Demonstrations on the Diseases of the Throat, Nose, and Ear are given daily at 2 P.M. and on Tuesday and Friday evenings at 6 P.M. Operations are performed almost daily at 9.30 A.M. Individual instruction is given in the examination of cases to students attending the hospital. Fees: one month's attendance, £1 1s.; three months, £2 2s.; perpetual, £5 5s. Detailed information may be obtained from the Hon. Secretary of the Medical Committee.

THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital was founded in 1838 and is situated in Grafton-street, Tottenham-court-road. The out-patient department is opened daily at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, and Thursdays at 9 A.M. Fee for one month's attendance at the hospital £1 1*s.*, and for three months £2 2*s.* During the forthcoming session practical demonstrations will be given by members of the staff on the diagnosis and treatment of diseases of the ear and respiratory passages. Each course may commence at any time.

THE HOSPITAL FOR WOMEN, Soho-square, W.—*Staff:* Consulting Physicians: Dr. Carter and Dr. Holland. Consulting Surgeon: Mr. Reeves. Consulting Surgeon Dentist: Mr. Canton. Gynæcologists: Dr. Richard Smith, Dr. Mansell-Moullin, Dr. Bedford Fenwick (in charge of out-patients), Dr. James Oliver, Dr. Dauber, and Dr. Stevens. Assistant Gynæcologist: Dr. Simson. Surgeon: Mr. Drew. Assistant Surgeon: Mr. McGavin. Surgeon Dentist: Mr. May. Anæsthetists: Mr. O. J. Ogle and Dr. M. Horne. Pathologist: Dr. Aarons. Registrar, Dr. Milligan. House Physician: Dr. Aubrey. In connexion with the out-patient department there has been for some years a well-organised Clinical Department. To meet the want increasingly felt by medical men of a more accurate knowledge of the diseases peculiar to women and of more extended opportunities for examining gynæcological cases gentlemen are appointed to act as clinical assistants to the gynæcologists to out-patients. The appointments are open to qualified medical men. The hospital contains 60 beds. In the out-patient department there were over 4000 new cases during the past year, the total number of out-patient attendances being 15,778 This large number affords exceptional opportunities for examining and studying most of the varieties of the diseases of women. Clinical assistants are entitled to receive notice of all operations performed within the hospital, and every facility is afforded them by the gynæcologists in the out-patient department of obtaining experience in diagnosis and treatment and the practical use of instruments. Fee for one month £3 3*s.*; for each subsequent month £2 10*s.* 6*d.* A certificate is given at the end of a three months' course. Applications should be made to the Dean.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. (80 beds.)—This hospital provides accommodation for 80 in-patients. Expenditure for 1905 £6500; income (including legacies, £1520), £6165. The attendance of out-patients averages 27,000 annually.

Staff.—Consulting Physicians: Dr. Horace Dobell, Dr. P. J. Hensley, and Professor D. W. Finlay. Physicians: Dr. W. H. White, Dr. Oswald Browne, Dr. A. Davies, Dr. J. Calvert, Dr. M. Leslie, and Dr. J. H. Drysdale. Assistant Physicians: Dr. A. G. Phear, Dr. H. E. Symes Thompson, and Dr. J. Graham Forbes. Consulting Surgeons: Mr. J. Hutchinson and Mr. Pearce Gould. Surgeon: Mr. W. Turner. Resident Medical Officer: Dr. P. A. Dingle. House Physician: Dr. A. S. Hosford. Secretary: Mr. A. T. Mays.

ROYAL EAR HOSPITAL, Dean-street, Soho. (Founded 1816.)—Courses of instruction of a practical character in Diseases of the Ear and Nose are given by the members of the staff throughout the year. Clinical assistants are also appointed. The new hospital is now in full working order. Students may join at any time. For information address the Honorary Secretary of the Medical Board, Mr. T. H. Chaldecott.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N. —Consulting Physicians: Sir S. Wilks, Bart., and Dr. R. Barnet. Consulting Surgeon: Mr. J. F. Macready. Physicians: Dr. E. C. Beale, Dr. C. E. Beevor, Dr. H. W. Syers, Dr. A. Morison, Dr. T. J. Horder, and Dr. Symes Thompson. Obstetric Physicians: Dr. G. F. Blacker and Dr. R. H. Bell. Physician for Skin: Dr. A. Whitfield. Surgeons: Mr. P. T. B. Beale, Mr. G. B. M. White, Mr. E. C. Stabb, Mr. V. W. Low, and Mr. Arthur Edmunds. Ophthalmic Surgeon: Mr. A. S. Morton. Throat and Ear Surgeons: Mr. E. B. Waggett and Mr. Frank Rose. Dental Surgeon: Mr. C. Peyton Baly. This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the Honorary Staff there are two resident House Physicians, three resident House Surgeons, four Anæsthetists, Registrar, Pathologist, and Casualty Officer. The hospital contains 162 beds which are now fully occupied. The large rectangular and circular wards, each of which contains 24 beds, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. The second operation theatre and a new surgery with observation wards are now in full working order, bringing the hospital thoroughly up to date. An electrical department is being arranged. Medical practitioners are cordially invited to see the general and special practice of the hospital. Clinical assistants (*qualified*), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. Further particulars from Dr. T. J. Horder, honorary secretary, Medical Committee, 141, Harley-street, W.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, N.W.—Physicians for In-patients: Miss Cock, M.D., and Miss Walker, M.D. Surgeons for In-patients: Mrs. Boyd, M.D., and Miss Aldrich-Blake, M.D., M.S. Physicians and Surgeons for Out-patients: Miss Webb, M.B., Miss Macdonald, M.B., Miss Chadburn, M.D., B.S., and Miss Anderson, M.D., B.S. Children's Department: Mrs. Flemming, M.D. Ophthalmic Surgeon: Miss Sheppard, M.B. Assistant Physicians for Out-patients: Miss Woodcock, M.D., Miss Chesney, M.B., Miss Ivens, M.D., B.S., Miss Sturge, M.D., and Miss Turnbull, M.D. Senior Obstetric Assistant: Miss Turnbull, M.D Anæsthetists: Miss Browne, L.S.A., Miss Thorne, M.D., and Miss Turnbull, M.D. A considerable number of the students hold posts in the New Hospital under the visiting staff, and in return for much valued clinical teaching they do the work assigned to students in the wards of a general hospital. Secretary: Miss M. M. Bagster.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1673).—Physicians: Dr. Fenwick, Dr. Parkinson, and Dr. Addinsell. Surgeon: Sir William J. Collins. Assistant Surgeon: Mr. H. J. Paterson. Dental Surgeon: Mr. A. Alexander. The hospital contains 110 beds. The in-patients in 1905 were 1257, and the out-patients and casualties numbered 25,071 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Special departments for Ophthalmology and Gynæcology. Operations: Mondays and Thursdays, 3.30 P.M. Classes will be held during the winter and summer sessions for students preparing for the final examinations at the Colleges and the Universities. Appointments, vacancies for which are advertised in the medical journals: Medical and Surgical Registrars and Pathologist; Resident Medical Officer, Assistant Resident Medical Officer, and Assistant House Surgeon. For particulars as to hospital practice and classes apply at the hospital.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—The hospital, with the Finchley branch, contains 200 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday at 2.30 P.M. In- and out-patient practice and electrical-room treatment at that hour. Physicians: Dr. Hughlings Jackson, Dr. Buzzard, Dr. Bastian, Sir William Gowers, Dr. D. Ferrier, Dr Ormerod, and Dr. Beevor. Physicians for Out-patients: Dr. Tooth, Dr. James Taylor, Dr. J. S. Risien Russell, and Dr. Aldren Turner. Assistant Physicians: Dr. Batten, Dr. J. S. Collier, and Dr. F. Buzzard. Surgeons: Sir Victor Horsley, Mr. C. A. Ballance, Mr. Donald J. Armour, and Mr. Percy W. G. Sargent. Ophthalmic Surgeon: Mr. Marcus Gunn. Aural Surgeon: Mr. A. E. Cumberbatch. Laryngologist: Sir Felix Semon. Gynæcologist: Dr. Walter Tate. Anæsthetist: Dr. Llewelyn Powell. Pathologist: Dr. Gordon Holmes. Registrar: Dr. C. M. H. Howell. House Physicians: Dr. S. A. K. Wilson, Dr. D. W. C. Jones, and Dr. G. Hall. The hospital is a school of the University of London and has been recognised by the Conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, and hospital practice should be addressed to the Secretary at the hospital.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—Consulting Physician: Dr. George B. Brodie. Consulting Surgeon: Mr. Alfred Willett. Physicians to In-patients: Dr. W. S. A. Griffith, Dr. W. Rivers Pollock, and Dr.

W. J. Gow. Physicians to Out-patients: Dr. T. W. Eden. Dr. C. Hubert Roberts, and Dr. Arthur F. Stabb. This hospital, which has been recently again enlarged and in which many important improvements have been carried out, receives over 1600 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. Fees: Medical Students, £8 8s. for four weeks; Qualified Medical Practitioners, £8 8s. for four weeks. Pupil Midwives (including board and lodging), £35 for five months; Pupil Nurses (including board and lodging), £24 for sixteen weeks. The new residence for students and qualified practitioners is opposite the hospital, with which it is in telephonic communication. Terms for residence and full board 35s. per week. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital. Students can join at any time, but preferably on the first Monday in each month.

THE SEAMEN'S HOSPITAL SOCIETY possesses two hospitals —the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds. It has also two Dispensaries—one in the East India Dock-road and the other at Gravesend—from which the patients are transferred to the hospitals. The London School of Tropical Medicine and the London School of Clinical Medicine are both under the auspices of the Seamen's Hospital Society, and information concerning these will be found upon p. 625. The medical staff administering the hospitals of the Seamen's *Hospital Society* is as follows:— Consulting Physician: R. Barnes. Visiting Physicians: Sir P. Manson, R. T. Hewlett, G. Rankin, and A. Duncan. Consulting Surgeon: W. J. Smith. Visiting Surgeons: W. Turner, J. Cantlie, L. H. McGavin, and A. Evans. Ophthalmic Surgeon: L. V. Cargill. Dental Surgeon: K. W. Goadby. Anæsthetist: K. Steele. Medical Officer East India Dock-road Dispensary: W. H. F. Oxley. Surgeon Gravesend Dispensary: C. E. Robbs. Secretary: P. Michelli.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C., contains 222 beds, divided into 95 medical, 105 surgical, and 22 for special and infectious cases, besides 33 beds at the convalescent branch, Highgate. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students who have completed four years of medical study and also to qualified medical men. The medical staff are recognised by the University of London as teachers in Diseases of Children. Appointments are made every three months to six medical clerkships, which are open to students of the hospital. Lectures or demonstrations are given once or twice every week during both winter and summer sessions, which qualified practitioners are invited to attend free of charge. There is a museum in connexion with the hospital. The sessions are of ten weeks' duration, and begin in October, January, and March. Fees for hospital practice, three months, 3 guineas: perpetual ticket 5 guineas. Prospectuses and further information will be forwarded on application to the Secretary at the hospital.

Staff.—Consulting Physicians: Dr. W. H. Dickinson, Dr. W. B. Cheadle, Sir Thomas Barlow, Bart., Dr. D. B. Lees, and Dr. F. G. Penrose. Physicians: Dr. A. E. Garrod, Dr. A. F. Voelcker, Dr. W. S. Colman, and Dr. F. E. Batten. Assistant Physicians: Dr. G. F. Still, Dr. F. J. Poynton, Dr. Robert Hutchison, Dr. H. Thursfield, and Dr. T. Thompson. Consulting Surgeons: Sir Thomas Smith, Bart., Mr. Howard Marsh, Mr. Edmund Owen, Mr. John Morgan, and Mr. Bernard Pitts. Surgeons: Mr. W. Arbuthnot Lane, Mr. Thomas H. Kellock, Mr. H. Stansfeld Collier, and Mr. Francis J. Steward. Assistant Surgeons: Mr. Edred M. Corner, Mr. G. E. Waugh, and Mr. H. A. T. Fairbank. Ophthalmic Surgeon: Mr. J. Herbert Parsons. Aural Surgeon: Mr. G. E. Waugh. Surgeon-Dentist: Mr. W. Warwick James. Radiographer: Dr. Ironside Bruce. Local Medical Officer for Cromwell House: Dr. A. M. Henderson. Medical Registrar: Dr. Langmead. Clinical Pathologist and Bacteriologist: Mr. Graham Forbes. Anæsthetists: Dr. R. T. Bakewell, Dr. R. W. Collum, and Mr. Graham Scott. Resident Medical Superintendent: Mr. O. L. Addison. Secretary: Mr. Stewart Johnston.

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields, 1854–1899), City-road, E.C.—133 beds. This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. In 1905 there were 2051 in-patients, the new out-patients were 42,335, and the attendances were 127,873. Operations are performed daily from 10 A.M. to 1 P.M. and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3s.; perpetual, £5 5s. *Courses of instruction on the following subjects are* given at the hospital periodically: (1) the use of the ophthalmoscope; (2) errors of refraction; (3) external diseases of the eye; (4) *surgical anatomy of the eye*; (5) pathology of the eye; (6) motor anomalies; (7) examination of the eye; (8) operative surgery: (9) x ray work; and (10) clinical lectures. A composition fee of £10 10s. will entitle students of the hospital to a perpetual ticket and will admit them once to all the above lectures and demonstrations except the classes on operative surgery and x ray work. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary.

Staff.—Consulting Physician: Sir Stephen Mackenzie. Consulting Surgeons: Mr. J. Hutchinson, Mr. J. Couper, Mr. E. Nettleship, Mr. J. Tweedy, and Mr. W. Tay. Physician: Dr. J. Taylor. Surgeons: Mr. R. M. Gunn, Mr. W. Lang, Mr. J. B. Lawford, Mr. A. S. Morton, Mr. E. T. Collins, and Mr. W. T. H. Spicer. Assistant Surgeons: Mr. P. Flemming, Mr. J. H. Fisher, Mr. A. Lawson, Mr. C. D. Marshall, Mr. J. H. Parsons, and Mr. C. Worth. Medical Officer to the X Ray Department: Mr. J. M. Davidson. Curator and Librarian: Mr. G. Coats. Senior House Surgeon: Mr. E. E. R. Sawrey. Second House Surgeon: Mr. C. Goulden. Third House Surgeon: Mr. A. C. Hudson. Refraction Assistants: Mr. T. Phillips, Miss E. J. Moffett, Miss W. Thorp, and Mr. G. T. Mould.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 40 beds. Patients, who number 11,000 annually, are seen at 1 P.M., and operations performed daily at 2 P.M. The following are the days of attendance of the *surgeons*: Mr. Hartridge and Mr. Grimsdale, Mondays and Thursdays; Mr. Roll *and* Mr. McMullen, Tuesdays and Fridays; and Mr. Dodd and Mr. Brewerton, Wednesdays and Saturdays. The practice of the hospital is open to practitioners and students. Fees for six months, £3 3s.; *perpetual*, £5 5s. Students of the hospital are eligible for the posts of house surgeon and clinical assistants. Special demonstrations and lectures will be given during the session, commencing in October; *for details* see weekly journals. Clinical Assistants (who must be duly qualified) to the Surgeons are appointed for periods of six months. Secretary: Mr. John H. Johnson.

ROYAL EYE HOSPITAL, St. George's-circus, Southwark, S.E.—There are 40 beds and 2 cots. There were 72,696 attendances in the Out-patient Department last year and the new patients numbered 25,635. Operations are performed and out-patients are seen daily at 9 A.M. and 2 P.M. The following are the days of attendance:— Afternoons: Mr. M. M. McHardy, Tuesdays and Thursdays; Sir William J. Collins, Mondays and Wednesdays; Mr. L. V. Cargill, Tuesdays and Saturdays; and Mr. R. Doyne, Mondays and Fridays. Mornings: Mr. E. Brooksbank James, Mondays and Thursdays; Mr. A. W. Ormond, Wednesdays and Saturdays; Mr. H. Willoughby Lyle, Tuesdays and Fridays. Qualified practitioners and students are admitted to the practice of the hospital upon the recommendation of the medical staff. Courses of instruction in Ophthalmology will be given during October, November, and December, 1906. Lectures will be delivered on Monday, Wednesday, and Friday evenings at 8 P.M. In addition special lectures or clinical demonstrations will be given by the hospital staff on dates to be announced. Fee for the course, £2 2s.; including three months' hospital practice, £3 3s. Tutorial or coaching classes for the various examinations arranged as far as possible to suit candidates. Further particulars may be obtained from the honorary secretary, Mr. A. W. Ormond.

TOTTENHAM HOSPITAL, South Tottenham, N.—This general hospital is in the midst of a densely-populated neighbourhood of about half a million inhabitants. It contains medical and surgical wards and a ward for children, having in all 120 beds. Over 1260 patients were treated in the wards last year and there were over 21,800 new out-patients. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, medical electricity and radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction is given daily in the wards and out-patient departments in connexion with the North-East London Post-graduate College attached (see p. 626). There are three Resident Medical Officers, and Clinical Assistants are appointed under certain conditions. Further particulars in regard to the hospital may be obtained from Mr. H. W. Carson, Secretary to the Medical Committee, 26, Welbeck-street, W.; or from Dr. A. J. Whiting, Dean of the North-East London Post-Graduate College, 142, Harley-street, W.

Staff.—Consulting Physicians: Sir James Reid, Bart., and Dr. Percy Kidd. Consulting Surgeons: Mr. J. Langton, Mr. G. Lichtenberg, and Mr. Hooper May. Physician: Dr. R. Murray Leslie. Physician to Out-patients: Dr. G. P. Chappel. Assistant Physician: Dr. A. J. Whiting. Surgeons: Mr. Walter Edmunds and Mr. H. W. Carson. Gynæcologist: Dr. A. E. Giles. Surgeon to Ear, Nose, and Throat Department: Mr. H. W. Carson. Ophthalmic Surgeon: Mr. R. P. Brooks. Physician for Skin Diseases: Dr. G. Norman Meachen. Medical Officer in charge of the X Ray and Electrical Departments: Mr. R. Higham Cooper. Dental Surgeon: Mr. W. Donston. Anæsthetics: Mr. A. De Prenderville, Mr. F. Herbert Wallace, and Dr. H. Vaughan Pryce. Pathologist: Dr. G. Basil Price. Medical Registrar: Dr. G. N. Meachen. Surgical Registrar: Mr. C. W. Hutt. Secretary: Mr. F. W. Drewett.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—This hospital has 26 beds and possesses facilities for clinical teaching daily. Classes of instruction in the use of the Ophthalmoscope, with demonstrations on cases, and also classes on Refraction, are given during the winter months, commencing in October. The out-patient work begins at one o'clock and operations are performed daily between one and four o'clock.

Staff.—Consulting Physician: Sir Dyce Duckworth. Surgeons: Mr. T. Brittin Archer, Mr. Ernest Clarke, Mr. A. P. L. Wells, Mr. H. Parker, and Mr. N. M. MacLehose. Assistant Surgeon: Mr. W. I. Hancock. Physician: Mr. Charles O. Hawthorne. Pathologist: Mr. Stephen Mayou. House Surgeon: Mr. J. M. Pollard. Dentist: Mr. E. P. May. Secretary: Mr. H. R. S. Druce.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C. Rebuilt 1905.—The out-patient practice is open to the medical profession at the following times: Every day, from 2 to 4 P.M., and every evening (except Saturday) 6 to 8. Specially selected Clinical Demonstrations, also demonstrations on the different diseases presenting themselves in the out-patient department, followed by Lectures, will also be given. The x ray department is in operation on Monday and Friday afternoons.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, Henrietta-street, Covent-garden. Established 1860. New Hospital opened, 1882.—Honorary Surgeons: Mr. F. Swinford Edwards and Mr. P. J. Freyer. Assistant Surgeons: Mr. John Pardoe and Mr. J. W. Thomson Walker. The hospital contains 24 beds for men and 2 beds for women and children. Consultations are held and operations are performed each Wednesday and Friday at 2 P.M. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 24; average out-patients seen daily, 100.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Physicians: Dr. Eustace Smith, Dr. J. A. Coutts, Dr. Morley Fletcher, and Dr. E. Graham Little. Surgeons: Mr. H. Betham Robinson and Mr. Cuthbert S. Wallace. Assistant Physicians: Dr. A. M. Gossage, Dr. Clive Riviere, Dr. W. P. S. Branson, and Dr. T. Fisher. Assistant Surgeons: Mr. W. Trotter and Mr. W. H. Bowen. Ophthalmic Surgeon: Mr. W. I. Hancock. Dental Surgeon: Mr. E. S. Pierrepont. Medical Officer for the Electrical Department: Dr. G. Graham. Medical Officer for the Casualty Department: Dr. H. Pritchard. Resident Medical Officer: Dr. S. A. Owen. House Physician: Mr. C. E. Iredell. House Surgeon: J. W. Parker. Secretary: W. M. Wilcox. The hospital maintains 119 cots, and on an average 259 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months, subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to Mr. H. Betham Robinson or to W. M. Wilcox, the Secretary.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physicians: Dr. J. F. Goodhart, Dr. Frederick Taylor, and Dr. Nestor Tirard. Physicians: Dr. Frederick Willcocks and Dr. J. Charlton Briscoe. Physicians in charge of Out-patients: Dr. J. R. C. Whipham and Dr. D. Forsyth. Consulting Surgeons: Sir H. G. Howse, Mr. R. Clement Lucas, Mr. G. H. Makins, Mr. F. S. Eve, Mr. F. C. Abbott, and Mr. A. H. Tubby. Surgeons: Mr. C. H. Fagge and Mr. H. S. Clogg. Surgeons in charge of Out-Patients: Mr. Sydney Scott and Mr. W. M. Mollison. Dental Surgeon: Mr. Denison Pedley. Ophthalmic Surgeon: Mr. Sydney Stephenson. House Physician: Mr. C. K. Attlee. House Surgeon: Mr. Hamilton Irving. Assistant House Surgeon: Mr. H. F. Marshall. Pathologist: Mr. A. N. Leathem. Dispenser: Mr. F. A. Hocking. Radiographer: Mr. R. H. Cooper.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W.—The hospital contains 104 beds (of which 16 are not available through lack of funds) and has a large out-patient department (over 1000 weekly); the home at Broadstairs has 50 beds. Consulting Physicians: Sir William Broadbent, Bart., Sir Francis Laking, and Dr. Ridge Jones. Consulting Surgeons: Mr. Cowell, Mr. Pickering Pick, and Mr. D'Arcy Power. Physicians: Dr. Montague Murray, Dr. Walter Carr, Dr. Humphry D. Rolleston, Dr. William James Fenton, Dr. Edmund Ivens Spriggs, and Dr. A. J. Jex-Blake. Physician to Skin Department: Dr. J. M. H. MacLeod. Surgeons: Mr. Raymond Johnson, Mr. H. F. Waterhouse, and Mr. Rupert H. Bucknall. Surgeons to the Out-patients: Mr. Percy W. G. Sargent, Mr. Joseph Cunning, and Mr. W. Fedde Fedden. Ophthalmic Surgeon: Mr. C. Devereux Marshall. Dental Surgeon: Mr. C. E. Wallis. Anæsthetists: Dr. E. Chittenden Bridges, Dr. Randolph Grosvenor, and Dr. Reginald H. Tribe. House Surgeon: Mr. R. H. Humphry. House Physician: Dr. G. Laurence. Secretary: Mr. H. G. Evered. Out-patients are seen as under:—Diseases of the Eye: Wednesday, 2 P.M. Diseases of the Skin: Wednesday, 2 P.M. Whooping-cough Cases: Fridays, 9.30 A.M. Medical and Surgical Cases: Monday and Thursday mornings at 9 A.M.; any afternoon except Wednesday and Saturday at 12.30 P.M. Dental Cases: Wednesday mornings at 9.30 A.M. Accidents and urgent cases are admitted at any time.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 159 beds, all of which are at present in use. About 2600 in-patients and 37,000 out-patients, whose attendances number 100,000, are treated annually. Physicians: Dr. D. W. C. Hood, Dr. Seymour Taylor, and Dr. A. P. Beddard. Physician for Diseases of Women: Dr. J. A. Mansell-Moullin. Surgeons: Mr. C. B. Keetley, Mr. F. Swinford Edwards, Mr. S. Paget, and Mr. L. A. Bidwell. Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Assistant Physicians: Dr. E. A. Saunders, Dr. H. Davis, and Dr. A. E. Russell. Assistant Physician for Diseases of Women: Dr. G. H. Drummond Robinson. Assistant Surgeons: Mr. A. Baldwin and Mr. Donald Armour. Surgeon-Dentist: Mr. H. Lloyd Williams. Physician in charge of Throat and Nose and Aural Department: Dr. J. B. Ball. Assistant Physician Aural Department: Dr. H. J. Davis. Physician in charge of Children's Department: Dr. E. A. Saunders. Surgeon in charge of Orthopædic Department: Mr. C. B. Keetley. Pathologist: Dr. G. C. Low. Dermatologist: Dr. P. S. Abraham. Officers in charge of the X Ray Department: Mr. Chisholm Williams and Dr. D. Arthur. Administrators of Anæsthetics: Messrs. T. Gunton Alderton, Rickard W. Lloyd, E. W. Lewis, and G. P. Shuter. Electrician: Dr. H. Davis. Secretary of the Hospital: Mr. R. J. Gilbert; of the College: Mr. H. Grant Rawle. Attached to th[illegible]ital is the West London

Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms daily and demonstrations are given in the wards on certain fixed days. Post-graduate lectures and demonstrations are given daily except Saturdays; notice of the commencement of each course is advertised in the medical journals. Special Classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Surface Anatomy, Blood and Urine, Clinical Microscopy, and Tropical Medicine. The accommodation for post-graduates consists of a large lecture room, together with reading and writing rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology, a class being held every month. The fees for hospital practice, including lectures, are £5 5*s.* for three months or £12 12*s.* for one year. The certificate of the hospital is accepted by the Admiralty, War Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Mr. L. A. Bidwell, at the hospital.

North-Eastern Hospital for Children, Hackney-road, Bethnal-green, E. (Telephone 305 Dalston). For the sick children of the poor under 12 years of age. Established 1867.—125 beds. During the past year 1685 in-patients and 27,733 out-patients (representing 75,637 attendances and including 8967 accident and emergency cases) were relieved, 535 of the in-patients being under two years of age. Consulting Physicians: Dr. A. E. Sansom, Dr. W. Cayley, Dr. W. Pasteur, and Dr. W. A. Wills. Consulting Surgeons: Mr. Jonathan Hutchinson, Mr. Waren Tay, Mr. R. J. Godlee, Mr. Bilton Pollard, and Mr. H. Percy Dean. Physicians: Dr. James Taylor, Dr. J. Porter Parkinson, and Dr. George Carpenter. Assistant Physicians: Dr. Charles Bolton and Dr. Sheffield Neave. Surgeons: Mr. Douglas Drew and Mr. Ewen O. Stabb. Assistant Surgeons: Mr. P. Lockhart Mummery and Mr. J. M. G. Swainson. Ophthalmic Surgeon: Mr. Sydney Stephenson (Thursday, 2.30 P.M.). Physician in charge of Skin Department: Dr. H. G. Adamson. Dental Surgeon: Mr. S. F. Rose (Tuesday, 9.30 A.M., and Friday, 2.30 P.M.). Medical Radiographer: Mr. Chaworth Nolan. Pathologist and Bacteriologist: Mr. W. A. Milligan. Matron: Miss Bushby. Secretary: Mr. T. Glenton-Kerr. The surgeons attend on Wednesdays and Saturdays at 2 P.M. and Fridays at 9.30 A.M.; the physicians daily at 2 P.M., except Saturday, 9.30 A.M. Applications for permission to attend the practice of the hospital should be addressed to the secretary.

North-West London Hospital, Kentish Town-road.—Consulting Physician: Dr. Donald W. C. Hood. Consulting Surgeon: Mr. Frederic Durham. Physicians: Dr. Harry Campbell, Dr. W. Knowsley Sibley, and Dr. G. A. Sutherland. Assistant Physician: Dr. C. O. Hawthorne. Surgeons: Mr. M. P. Mayo Collier, Mr. J. Jackson Clarke, and Mr. George Templeton. Assistant Surgeon: Mr. J. W. Thomson Walker. Physician for Diseases of the Skin: Dr. J. Herbert Stowers. Obstetric Physician: Dr. John Shaw. Ophthalmic Surgeon: Sir William J. Collins. Dental Surgeon: Mr E. Faulkner Ackery. Anæsthetists: Dr. G. A. H. Barton and (vacant). Resident Medical Officers: Mr. J. Ferguson and Mr. J. Braybrook Binns. The hospital, which was established in 1878, provides 50 beds. The average number occupied last year was 45. It is a general hospital. There are two spacious wards for men and women respectively. The children's ward contains 15 cots. There are two Resident Medical Officers—an honorarium at the rate of £50 per annum attaches to each post. Operation days, Monday and Thursday at 2.30 o'clock. Further particulars from the secretary at the hospital.

Royal Army Medical Corps (Volunteers) (London Companies), Calthorpe-street, Gray's Inn-road, W.C.—Officer Commanding: Lieutenant-Colonel Valentine Matthews. The Royal Army Medical Corps (Volunteers) bears the same relation to the Volunteer Army as the Royal Army Medical Corps bears to the regular Army. The course of training has the great advantage of affording, in addition to a knowledge of ordinary military duties, special ambulance instruction useful in all ranks of life. All students who are thinking of entering either of the public services are strongly recommended to join. The instruction received will be found of the greatest advantage to such as intend joining either the Royal Army Medical Corps or the Indian Medical Service on the completion of their hospital course, the work taught in the Royal Army Medical Corps (Volunteers) being practically the same as that taught at the Depôt, Royal Army Medical Corps, Aldershot, and in which an examination is held at the end of the four months' course there before the young officers are drafted to their different stations. A sound knowledge of the work, which can be obtained in the Royal Army Medical Corps (Volunteers) must necessarily be of great benefit to those going through the depôt and give a decided advantage over those who have had no previous military training. In addition to the drills of an ordinary infantry corps, the special training includes stretcher and wagon and cacolet drill; the use of improvised seats and stretchers; the use and application of bandages, splints, &c.; the duties of the *personnel* of a field ambulance; lectures by the officers on first aid to the injured, and on the elements of anatomy, physiology, hygiene, and nursing, which are so arranged as not to interfere with the lectures, &c., carried on at the various hospitals in London. The corps goes into camp for a week in the summer each year for field training. There is also a Shooting Club in the corps, in which instruction in, and facilities for, the practice of rifle shooting are given. There is a Transport Section in connexion with the corps, the members of which go through a course of instruction in riding and driving and transport work with the regular troops. There are also sections of Cyclists and Signallers. A Gymnastic and Boxing Class meets once a week at headquarters, under a professional instructor. Lectures are delivered during the winter session. The headquarters contain a fine drill-hall, mess-rooms, canteen, &c., where dinners, suppers, dances, and smoking concerts can be held at any time. The Adjutant will give any information respecting the above on application to the headquarters, Calthorpe-street, Gray's Inn-road, W.C.

Cooke's School of Anatomy, Physiology, and Operative Surgery, London.—The school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half-a-dozen students in the course of the year; these have special advantages both as regards Anatomy and Physiology. Charges are but slightly in excess of current charges and particulars are forwarded on application. By the decision of various examining bodies gentlemen rejected at their Anatomical and Physiological Examinations can get signed up for the supplementary work they are required to put in before re-examination. The operations of surgery are performed on the dead body and the courses are recognised for army promotion. The school possesses a good collection of physiological and chemical apparatus and candidates for the higher examinations receive special instruction in the more difficult subjects.

PROVINCIAL MEDICAL SCHOOLS AND HOSPITALS HAVING SPECIAL CLASSES AND FACILITIES FOR CLINICAL STUDY.[1]

The University of Birmingham (Faculty of Medicine).—An Ingleby Scholarship is annually awarded to the candidate obtaining the highest number of marks in Obstetric Medicine and Surgery and Diseases of Women and Children at the final M.B. examination. One or more Sydenham Scholarships are offered annually of the value of 40 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds 23 years on the day of election. The Scholarships are held for three years, subject to good behaviour. A Sands Cox Scholarship is offered annually of the value of 40 guineas. It may be held for three years, one-third being paid each year, subject to good behaviour. Queen's Scholarships of the value of £10 10*s.* are awarded at the end of the Second, Third, Fourth, and Final M.B., Ch.B. University examinations. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. The Walter Myers Travelling Studentship of the value of £150, tenable for one year at one of certain Universities in Germany, is open to graduates of the University of Birmingham whose age does not exceed

---

[1] For Scholarships see p. 597 et seq.

30 years. The medical courses qualify for the diplomas of all Licensing Bodies and for the degrees in Medicine and Surgery of British Universities. The Dental School, in conjunction with the General, Queen's, and Dental Hospitals, affords a complete curriculum for all Dental diplomas. The Library contains upwards of 28,000 volumes. Syllabuses containing full information as to the various courses of instruction, lecture days, and hours, fees, scholarships, &c., will be forwarded on application to Professor Barling, the Dean of the Medical Faculty. The Medical Session opens on Monday, Oct. 1st, 1906.

THE GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM.—The practices of these hospitals are amalgamated for the purpose of Clinical Instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 450 beds. 7000 in-patients and 90,000 out-patients are treated annually. The following appointments are open to past students. At the General Hospital: one resident medical officer, salary £70 a year (a degree in medicine is necessary); one resident surgical officer, salary £100 a year; two non-resident casualty assistant physicians, salary £50 a year; two non-resident surgical casualty officers, salary £50 a year; two non-resident anæsthetists, salary £50 a year; four house surgeons, office tenable for six months, salary £50 a year; one resident pathologist tenable for six months, salary £50 a year; three house physicians, tenable for six months, salary £50 a year; one resident medical officer at the Jaffray Branch Hospital, salary £150 a year; and one resident assistant at the Jaffray Hospital (post vacant early in April, July, October, and January, tenable for three months). At the Queen's Hospital, the Birmingham University; two non-resident physicians for out-patients, salary £50 a year; three non-resident surgeons for out-patients, salary £50 a year; one non-resident pathologist, salary £50 a year; three qualified house physicians (posts vacant in January and April, tenable for six months at a salary at the rate of £50; three qualified house surgeons (posts vacant in January and April, tenable for six months at a salary at the rate of £50); one qualified obstetric and ophthalmic house surgeon (post vacant in April and October, tenable for six months), salary at the rate of £50 a year; and one unqualified resident dresser (post vacant January, April, July, and October, tenable for three months).

Staff of General Hospital: Honorary Consulting Physicians: Right Hon. Sir W. Foster and Dr. E. Rickards. Honorary Consulting Obstetric Officer: Dr. E. Malins. Honorary Physician: Dr. R. Saundby, Dr. R. M. Simon, Dr. S. Wilson, and Dr. T. S. Short. Honorary Surgeons: Sir T. F. Chavasse, Mr. G. Barling, Mr. W. F. Haslam, and Mr. G. Heaton. Honorary Obstetric Officer: Dr. Thos. Wilson. Honorary Ophthalmic Surgeon: Mr. D. C. Lloyd-Owen. Aural Surgeon and Laryngologist: Dr. F. W. Foxcroft. Assistant Physicians: Dr. J. W. Russell and Dr. Stanley Barnes. Assistant Surgeons: Mr. A. Lucas and Mr. L. P. Gamgee. Assistant Obstetric Officer: Mr. J. T. Hewetson. Physician in Charge of Skin Department: Dr. A Douglas Heath. Anæsthetists: Dr. S. Haynes and Dr. W. J. McCardie. Casualty Assistant Physicians: Dr. W. H. Wynn and Dr. J. E. H. Sawyer. Surgical Casualty Officers: Mr. F. V. Milward and Mr. F. Barnes. Dental Surgeon: Mr. A. T. Hilder. Surgical Radiographer: Dr. J. Hall Edwards.

Staff of Queen's Hospital.—Consulting Physicians: Sir J. Sawyer and Dr. Suckling. *Consulting Surgeons:* Mr. F. Jordan, Mr. J. St. S. Wilders, Mr. F. Marsh, and Mr. Bennett May. *Consulting* Ophthalmic Surgeon: Mr. Priestley Smith. Physicians: Dr. Carter, Dr. Foxwell, and Dr. Kauffmann. Surgeons: Mr. Jordan Lloyd, Mr. J. T. J. Morrison, and Mr. Leedham Green. Ophthalmic Surgeon: Mr. W. Allport. Obstetric Officer: Dr. Purslow. Physicians for *Out-patients:* Dr. Stanley and Dr. Emanuel. Surgeons for Out-patients: Mr. Billington and Mr. Nuthall. Pathologist: office vacant.

UNIVERSITY COLLEGE, BRISTOL (FACULTY OF MEDICINE).—Extensive additions have been made to the Anatomical, Bacteriological, and Pathological Departments. Students of the College *are admitted* to the *Clinical* Practice of the Bristol Royal Infirmary and the Bristol General Hospital conjointly, and consequently both these institutions are open to all students. The Infirmary and the *Hospital comprise* between them a total of 470 beds; and both have very extensive out-patient departments, special departments for the Diseases of Women and Children, and of the Eye, Ear, and Throat, besides large out-door Maternity Departments and Dental Departments. Students may also attend the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is 614. Very exception facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of *Medical and Surgical* work. Each student has the opportunity of personally studying a large number of cases and of acquiring *practical skill in diagnosis* and treatment. The annual prize distribution will take place at the hand of Professor Alex. Macalister, F.R.S., of Cambridge, on Oct. 2nd.

Courses of Lectures.—Medicine: Professor F. H. Edgeworth and Professor J. Michell Clarke. Surgery: Professor C. A. Morton and Professor *James Swain. Anatomy:* Professor Edward Fawcett. Practical Anatomy: Demonstrators, Dr. E. W. Hey Groves and Dr. W. S. Vernon Stock. Physiology and Histology: Professor A. F. Stanley Kent. Demonstrator: Dr. Fortescue-Brickdale. Chemistry: Professor Morris W. Travers. Public Health: Dr. D. S. Davies. Midwifery: Professor W. C. Swayne. *Medical Jurisprudence:* Dr. R. Eager and *Dr. G. Parker.* Pathology and Morbid Anatomy: Professor I. Walker Hall. *Demonstrator: Dr. Carey F. Coombs.* Operative Surgery: Mr. J. Paul Bush. Practical Medicine: Professor Edgeworth and Professor Michell Clarke. Practical Surgery: Dr. R. G. Poole Lansdown. Practical Midwifery: Mr. D. C. Rayner. Materia Medica and Practical Pharmacy: Mr. C. C. M. Davis. Pharmacology and Therapeutics: Dr. Newman Neild. Biology: Professor S. H. Reynolds. Practical Chemistry: Professor Morris W. Travers. Practical Bacteriology: Professor A. F. Stanley Kent. Comparative Anatomy: Professor C. *Lloyd Morgan. Dental Anatomy and* Physiology, Dental Histology, and Dental Bacteriology: *Professor A. F. Stanley Kent. Dental Surgery* and *Practical* Dental Surgery: Mr. W. R. Ackland. Dental Mechanics and *Dental Metallurgy and Practical* Dental Metallurgy: Dr. C. A. Hayman. Composition fee for lectures and hospital practice, 133 guineas. Composition fee for Dental lectures and surgical practice, 75 guineas. Special six months' course for Diploma in Public Health. 1. Lectures on Public Health: *Dr. D. S. Davies.* 2. *Bacteriology:* Professor A. F. Stanley Kent. 3. Laboratory Course of Hygienic Chemistry: Mr. F. W. Stoddart. 4. Demonstrations on the Various Acts, Orders, By-laws, &c.: Mr. J. C. Heaven. 5. Practical Outdoor Sanitary Work: *Dr. D. S. Davies. Fee for the* entire course 25 guineas. Full information can be obtained *on application to the Dean, Professor* Edward Fawcett, University College, Bristol.

ROYAL INFIRMARY, BRISTOL (*Established 1735*).—*270 beds.* Honorary and Consulting Physicians: Dr. *W. H. Spencer, Dr. R. Shingleton Smith,* and Dr. H. Waldo. Honorary and Consulting Surgeons: Mr. E. C. Board, Mr. W. H. Harsant, and Mr. A. W. Prichard. Honorary and Consulting Ophthalmic Surgeon: Mr. F. Richardson Cross. Honorary Physicians: Dr. J. E. Shaw, Dr. A. B. Prowse, Dr. P. Watson Williams, and *Dr. F. H. Edgeworth.* Honorary Surgeons: Mr. J. Paul Bush, Mr. G. Munro Smith, Dr. J Swain, and Mr. T. Carwardine. Honorary Ophthalmic Surgeon: *Dr. Ogilvy. Honorary* Obstetric Physician: Dr. Walter Swayne. Honorary Dental Surgeon: Mr. W. R. Ackland. Honorary Assistant Dental Surgeon: Dr. Charles A. Hayman. Honorary Assistant Physicians: Dr. J. R. Charles and Dr. J. A. Nixon. Honorary *Assistant Surgeons:* Mr. H. F. Mole and Mr. E. H. E. Stack. Pathologist: Dr. I. Walker Hall. Honorary Demonstrator of Morbid Anatomy: Dr. J. J. S. Lucas. Honorary *Anæsthetist:* Mr. A. L. Fleming. Honorary Assistant Anæsthetist: Mr. S. V. Stock. Honorary *Skiagraphist: Mr.* James Taylor. House Surgeon and Senior Resident Medical Officer: Dr. A. Rendle Short. House Physician: Mr. A. L. *Sheppard.* Resident Obstetric Officer: Mr. F. H. Rudge. Anæsthetist and Junior House Surgeon: Mr. L. Shingleton Smith. Casualty Officer: Mr. A. J. Wright.

BRISTOL GENERAL HOSPITAL.—Honorary and *Consulting* Physician: Dr. A. J. Harrison. Honorary and Consulting Surgeons: Mr. Robert W. Coe, *Dr. George* F. Atchley, Mr. F. Poole Lansdown, Mr. Nelson C. Dobson, and Mr. Chas. F. Pickering. Physicians: Dr. E. Markham Skerritt, Dr. J. Michell Clarke, and Dr. George Parker. Surgeons: Mr. C. A. Morton, Dr. R. G. Poole Lansdown, Dr. J. Lacy Firth, and Dr. H. Greville Kyle. Physician Accoucheur: Dr. W. H. C. Newnham. Physician to Department for Diseases of the Skin: Dr. W. Kenneth Wills. Surgeon to the Throat and Nose: Dr. J. Lacy Firth. Ophthalmic Surgeon: Mr. Cyril H. Walker. Assistant Physicians: Dr. J. O. Symes and Dr. Newman Neild. Assistant Surgeon: Mr. E. W. H. Groves. Assistant Physician Accoucheur: Mr. D. C. Rayner. Anæsthetists: Mr. J. Freeman and Mr. Hedley Hill. Dental Surgeon: Mr. T. Taylor Genge. Pathologists: Dr. J. Michell Clarke and Dr. Newman Neild. Curator of Museum: Dr. Coombs. Bacteriologist: Dr. J. O. Symes. Skiagraphist: Dr. J. Ellington Jones.

Clinical Scholarships and Prizes.—These are open for competition only to "Perpetual" Clinical Students. 1. Scholarships and Prizes, open to all students of Bristol Medical School:—(*a*) University Entrance Scholarship of £50 and Haberfield Entrance Scholarship of £30. (*b*) Tibbitts Surgical Prize, £9 9*s.*; and two Martyn Pathological Prizes of £10 each. (*c*) A Gold Medal and a Silver Medal given by the committees of the two institutions. 2. Restricted to students who have done the necessary qualifying work at the Bristol Royal Infirmary: Suple Medical Prize (consisting of a Gold Medal, value 5 guineas, and 7 guineas in money); Suple Surgical Prize (consisting of a Gold Medal, value 5 guineas, and 7 guineas in money); Clark Prize, value £11 11*s.*; Crosby Leonard Prize in Clinical Surgery, value £7 7*s.*; and Augustin Prichard Prize in Surgical Anatomy, value £7 7*s.* 3. Restricted to students who have done the necessary qualifying work at the Bristol General Hospital:—Clarke Scholarship, a surgical scholarship of the value of £15; Sanders Scholarship, a scholarship of the value of £22 10*s.*; and the Marshall Prize, value about £12.

Resident Appointments.—There are five resident appointments at the Infirmary and five in the Hospital, and the Dressers reside in rotation, free of expense. The Maternity students also have rooms provided in the institutions.

Fees.—Medical Practice: three months, 4 guineas; six months, 7 guineas; one year, 12 guineas; perpetual, 20 guineas. Surgical Practice: three months, 4 guineas; six months, 7 guineas; one year, 12 guineas; perpetual, 20 guineas. Medical and Surgical Practice together in one payment: six months, 12 guineas; one year, 20 guineas; perpetual, 35 guineas. Dental Surgical Practice: one year, 7 guineas; perpetual, 12 guineas. The above fees include Clinical Lectures. Clinical Clerkship: 5 guineas for six months. Dressership: 5 guineas for six months. Museum fee: 3 guineas (composition on entrance), or 1 guinea annually. Dispensing Fee: 2 guineas. Students from other schools or qualified medical men wishing to attend Clinical Practice for short periods and not requiring certificates for such attendance may do so for the following fees:—Medical and Surgical Practice conjointly: one month, 2 guineas; two months, 3 guineas; three months, 4 guineas; and six months, 7 guineas.

Further information may be obtained on application to the Dean of the Faculty.

OXFORD: RADCLIFFE INFIRMARY.—At this hospital courses of instruction are conducted in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. Demonstrations of Pathology are given in the post-mortem room and at the Pathological Department, University Museum, by the Professor of Pathology. Practical Pharmacy is taught in the Infirmary Dispensary. The whole combined course of study at the museum and hospital is intended for students until they have passed the Second Conjoint Examination or the first Oxford M.B. The infirmary contains 130 beds.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in the special methods of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit. The composition fee for pupilship is 8 guineas.

UNIVERSITY COLLEGE, CARDIFF, SCHOOL OF MEDICINE.—All classes are open to both men and women students who may spend three out of their five years of medical study at Cardiff. The courses of study are recognised as qualifying for the Preliminary Scientific and Intermediate Examination in Medicine in the University of London and for the corresponding examinations in the other Universities. Students who are preparing for these examinations may compound for their courses by paying a fee of £57 10*s.*, while a composition fee of £41 10*s.* includes all the necessary courses for the first and second examinations for the Diploma of the Conjoint Board. In all cases the composition fees may be paid by instalments. Hospital instruction is given at the Cardiff Infirmary. The attention of students about to matriculate is drawn to the numerous entrance scholarships and exhibitions, varying in value from £10 to £30 per annum, offered for competition at University College, Cardiff, in September next, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. In the department of Public Health established in 1899 instruction is given qualifying for the D.P.H. examinations. Further information may be obtained from the Dean of the Faculty of Medicine.

Lecturers.—Physics: Professor A. L. Selby. Chemistry: Professor C. M. Thompson. Zoology: Professor W. N. Parker. Botany: Professor A. H. Trow. Anatomy: Professor David Hepburn. Physiology: Professor J. B. Haycraft. Materia Medica and Therapeutics: Dr. W. Mitchell Stevens. Bacteriology: Mr. H. A. Schölberg. Public Health and Hygiene: Dr. E. Walford and Dr. W. Williams. Midwifery: Dr. E. J. Maclean. Vaccination: Mr. H. A. Schölberg.

CARDIFF INFIRMARY.—Consulting Physicians: Dr. W. T. Edwards, Dr. William Taylor, and Dr. C. T. Vachell. Consulting Surgeons: Dr. Alfred Sheen and Dr. T. Wallace. Consulting Dental Surgeon: Mr. John C. Oliver. Physicians: Dr. F. W. Evans and Dr. H. R. Vachell. Surgeons: Mr. P. Rhys Griffiths, Mr. William Sheen, and Mr. J. Lynn Thomas, C.B. Assistant Physicians: Dr. A. E. Taylor, Dr. W. Mitchell Stevens, and Dr. Cyril Lewis. Assistant Surgeons: Mr. H. G. Cook, Mr. Cornelius A. Griffiths, and Mr. William Martin. Ear, Throat, and Nose Surgeon: Dr. D. R. Paterson. Electrical Department: Mr. William Martin. Ophthalmic Surgeons: Mr. J. T. Thompson and Mr. H. C. Ensor. Assistant Ophthalmic Surgeons: Mr. F. P. S. Cresswell and Mr. R. Russell Thomas. Gynæcologists: Dr. Ewen J. Maclean and Dr. E. Tenison Collins. Pathologist: Dr. W. Mitchell Stevens. Bacteriologist and Assistant Pathologist: Dr. H. A. Schölberg. Anæsthetists: Dr. Fredk. W. S. Davies, Dr. W. G. Williams, and Dr. Alex. Brownlee. Dental Surgeons: Mr. T. W. Kittow and Mr. Thomas Quinlan. Resident Medical Officer: Dr. S. H. West.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—A new wing has been added to accommodate the departments of physiology and bacteriology. It also contains a students' gymnasium and a set of Students' Union rooms. The new Royal Victoria Infirmary, containing upwards of 400 beds, has been recently opened by His Majesty King Edward VII. In the new infirmary adequate accommodation will be provided for the study of the various special subjects, in addition to the ordinary clinical work. The following Scholarships and Prizes are awarded annually:—Four University of Durham Scholarships, value £25, tenable for four years, for proficiency in Arts, awarded to full students in their first year. The Pears Scholarship, value £50 a year, tenable for three years. The Masonic Scholarship, value £15 a year, tenable for three years. The Dickinson Scholarship, value interest of £400, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value the interest of £400, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value the interest of £700, for Medicine. The Gibb Scholarship, value the interest of £500, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value the interest of £325, for Clinical Medicine and Clinical Surgery. The Luke Armstrong Memorial Scholarship, value the interest of £680, for Comparative Pathology. The Stephen Scott Scholarship in Surgery, value the interest of £1000. Heath Scholarship: The late Dr. George Yeoman Heath, President of the University of Durham College of Medicine, bequeathed the sum of £4000 to found a Scholarship in Surgery, the interest to be awarded every second year; the next award will be in 1908. The Gibson Prize, interest on £225, in the department of Midwifery and Diseases of Women and Children. At the end of each session Prizes of Books are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, Prosectors, and Assistant Demonstrators of Physiology and Pathology are elected yearly. Pathological Assistants, Assistants to the Dental Surgeon, Assistants in the Eye Department, Throat and Ear Department, and Skin Department, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Physicians: Dr. Drummond, Dr. Oliver, Dr. Limont, and Dr. Murray. Assistant Physicians: Dr. Beattie and Dr. Bolam. Surgeons: Mr. Rutherford Morison, Mr. Ridley, Mr. Martin, and Mr. H. B. Angus. Assistant Surgeons: Mr. J. V. W. Rutherford, Mr. Richardson, Mr. Leech, and Mr. Clay. Pathologist: Dr. Bolam. Dental Surgeon: Mr. R. L. Markham. Skin Department: Dr. Limont. Eye Department: Mr. Wardale. Throat and Ear Department: Mr. Ridley. Anæsthetist: Dr. W. D. Arnison. Medical Registrars: Dr. Moore Ede and Dr. Simpson. Surgical Registrars: Mr. G. G. Turner and Mr. J. W. Heslop. The infirmary contains 280 beds. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given by the Pathologist as opportunity offers. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Northumberland County Asylum, Morpeth. A special Course of Instruction is given in the City Hospital for Infectious Diseases by the Superintendent, the City Officer of Health, Mr. H. E. Armstrong. The sessions open on May 1st and Oct. 1st of each year.

THE SCHOOL OF MEDICINE: MEDICAL FACULTY OF THE UNIVERSITY OF LEEDS.—The Leeds General Infirmary, in connexion with this medical faculty, has accommodation for 524 in-patients, including 96 beds at "semi-convalescent" homes in the country. During the last year 6445 in-patients and 38,660 out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electrical, Finsen Light, and X-ray Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. The Public Dispensary, the Hospital for Women and Children, the Fever Hospital, the Maternity Home, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds Students. Twelve years ago the new buildings of the Medical School were opened. Placed closed to the Infirmary, the School of Medicine contains complete accommodation for the training of medical students upon the most approved modern methods. A very fine dissecting-room, extensive laboratories for Physiology and Pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large Library, and separate Museums for Pathology and Anatomy are some of the most striking features of the buildings. Provision for the convenience of students, in the shape of a common room, a refectory, &c., are made. The classes in Systematic and Practical Chemistry, Physics and Biology, are held in the Science and Arts Department of the University, in College-road. Two Entrance Scholarships are offered: one, of the value of £71 0*s.* 6*d.*, covering admission to all requisite lectures; and the other, of the value of 40 guineas, covering the cost of admission to the medical and surgical practice of the infirmary. Several valuable prizes are given at the end of each session. The following appointments at the Infirmary are annually open to students (for some of them, however, a registered legal qualification is required): Non-resident: clinical pathologist, £200; senior anæsthetist, £50; 5 anæsthetists, £25. Resident: medical officer, £150; surgical officer, £150; casualty officer, £125; ophthalmic, £100. These appointments are made annually and holders are eligible for re-election. Resident medical officer to the Ida Hospital, for six months; honorarium £30. Six house physicians, for six months; 7 house surgeons, for six and 12 months; 24 physicians' clerks, for six months; 24 surgeons' dressers, for six months; 16 ophthalmic and aural surgeons' dressers, for three months; 12 gynæcological ward clerks, for three months: 16 gynæcological out-patient clerks, for three months; 24 maternity clerks, for one month; 24 assistant physicians' clerks, for three months; 8 dermatological clerks, for three months; 8 laryngological clerks, for three months; 24 assistant surgeons' dressers, for three months; 8 assistant ophthalmic surgeons' dressers, for three months; 24 dressers in the casualty-room, for three months; 24 post-mortem room clerks, for three months; 8 laboratory assistants, for three months. There are appointments open to students in other medical institutions in the town and also in the West Riding (Lunatic) Asylum.

THE UNIVERSITY OF LIVERPOOL: FACULTY OF MEDICINE.—Students may enter for the degrees of the University of Liverpool or study for the degrees and qualifications of the various other licensing bodies. The conditions as to degrees will be found on p. 553 under the heading of the University of Liverpool.

Medical School Buildings.—Spacious and well-equipped class-rooms and laboratories have been erected for the practical study of all the important scientific subjects which form the basis of medicine. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. The most recent additions are the Johnston Laboratories for Experimental Medicine, Bio-chemistry, and Comparative Pathology and the new building for Anatomy, Surgery, Toxicology, Ophthalmology and Dental subjects, which has just been completed. The departments of Physiology and Pathology are accommodated in the large block provided by the generosity of the late Rev. S. A. Thompson Yates in 1898. The Anatomical department is situated in a separate block and has a complete suite of rooms, including a large and well-stocked museum and a well-lighted dissecting room on the upper floor measuring 70 by 40 feet.

Hospitals.—The Clinical School of the University now consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye and Ear Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of 1127 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access from the University; those which are situated at any distance are readily reached by the tramway service of the city. The period of hospital practice extends over the last three years of medical study. During the first two years of this period no student will be permitted to change his attendance from one general hospital to another except at the commencement of an academic term. It is a regulation of the school that not more than five of the six terms of these two years shall be spent at any single general hospital. During the final year of hospital practice a student is permitted to attend the practice of all the general hospitals without restriction. The regulations demand only that his attendance shall be regular and to the satisfaction of the hospital's board. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school. These appointments (20) in most cases carry salaries ranging from £60 to £100 per annum. Applications for further information regarding the Clinical School should be addressed to the Dean of the Faculty of Medicine.

Fellowships and Scholarships.—Fellowships, scholarships, and prizes of over £1000 are awarded annually. A Holt Fellowship in Pathology and Surgery of the value of £100 for one year is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the pathological department. A Holt Fellowship in Physiology, awarded under similar conditions of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, also of the value of £100 for one year. An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynæcological Pathology (£100 a year, renewable). A Stopford Taylor Fellowship (£100 a year, renewable) in Dermatology. A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical Pathology. Two Lyon Jones Scholarships of the value of £21 each for two years are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students, on the subjects of the First M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, on the subjects of Anatomy, Physiology, and Therapeutics. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1907 the subject will be Clinical Medicine. The Torr Gold Medal in Anatomy, the George Holt medal in Physiology, the Kanthack Medal in Pathology, the Robert Gee Book Prize, of the value of £5, for Children's Diseases, and numerous Class Prizes are awarded annually.

Entrance Scholarships. — Two Robert Gee Entrance Scholarships of the value each of £25 per annum for two years are offered annually for competition. The holder is required to take out the Science Course for the University Degree in Medicine. Communications should be addressed to the Dean, Professor Benjamin Moore, The University, Liverpool.

School of Tropical Medicine.—Courses of instruction are given in Tropical Diseases, particulars regarding which may be obtained from Mr. A. H. Milne, B 10, Exchange-buildings, Liverpool. A diploma in Tropical Medicine is now granted by the University.

School of Veterinary Medicine.—A school of Veterinary Medicine in connexion with the University was opened in October, 1904; full courses of instruction for the Veterinary Curriculum will be provided and students will be prepared for the M.R.C.V.S. A diploma in Veterinary Hygiene is now granted by the University.

Public Health Department.—This is located in a separate building known as Ashton Hall in which full courses of instruction are given to D.P.H. students for the D.P.H. of the University.

Special Diplomas.—The University has instituted diplomas in Anatomy, Bacteriology, Bio-chemistry, and Parasitology. A special course of study of three terms' duration is required in the subject chosen for the diploma and allied subjects.

School of Pharmacy.—Complete courses of instruction are provided adapted to the requirements of candidates preparing for either the Minor or Major Examinations of the Pharmaceutical Society of Great Britain.

Prospectuses and further information may be had on application to the Registrar, University of Liverpool.

THE VICTORIA UNIVERSITY OF MANCHESTER: MEDICAL FACULTY.—This medical school is located in a large building, which forms a part of the University. It is provided with large dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, a large extension of the school buildings was made in 1895. The greater part of the new buildings is devoted to the departments of physiology, pathology, toxicology, anatomy, and public health. The physiological department occupies more than half of the new buildings, and includes a large lecture theatre, accommodating 350 students, with preparation and diagram rooms adjacent to it, and a research laboratory fitted with the necessary apparatus for the use of advanced students, research scholars, or practitioners of medicine undertaking the investigation of some special subject. In the new pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. In the toxicological department there is a large laboratory, capable of accommodating 50 students, lighted from both sides and also from the roof, completely equipped with all that is necessary for the practical teaching of toxicology; also a small laboratory for private research, containing the apparatus and fittings necessary for investigations in toxicological chemistry. In the public health department suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology. A large room is provided in the new buildings for a museum of apparatus, models, plans, and other sanitary appliances for the practical instruction of the students, together with a special library of works on State medicine, hygiene, vital statistics, and sanitary engineering. In addition, a large lecture theatre for general purposes, accommodating 250 students, has been provided, and the existing accommodation for students is supplemented by the provision of a larger common room. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, as well as in a fever hospital, a lunatic asylum, and a convalescent home. Medical and Surgical Clinical Classes are conducted in the infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary. The following entrance scholarships are offered for award to persons of either sex proposing to enter a medical course of study at the University:—Seaton—One of £40, tenable for two years. Subjects: Greek and Latin Translation at sight, and Prose Composition. Credit given for knowledge of Mathematics (Geometry and Algebra); Elements of English Language, Literature, and History; French and German. Rogers.—One of £40, tenable for two years. Subjects as in Seaton. Dalton.—Two of £40, tenable for two years. Subjects: Geometry (Euclid I.—IV., and VI., or the subjects thereof); Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles); Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics, Elements of English Language, Literature, and History; French and German. Cartwright.—£35 per annum, tenable for three years. Subjects as in Dalton. Hulme.—£35, tenable for three years. Subjects: English Language (Grammatical Structure and Outlines of its History); English Literature (an essay on some subject of English literature); and Modern History (Outlines of English History and Geography); with at least two of the following: Latin (Translation at sight, Grammar, and Easy Composition); Greek (ditto); French (ditto); German (ditto). Credit given for knowledge of Mathematics (Geometry and Algebra). Dora Muir.—£25 per annum, tenable for three years (open to women only). Candidates may select such of the subjects as they desire from amongst those set for the other Entrance Scholarships. James Gaskill.—£35, tenable for two years. Subjects: Mathematics, Geometry (the substance of Euclid I.—IV. and VI.), Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles), Elementary Mechanics, Chemistry. Credit given for knowledge of Classics, Elements of English Language, Literature, and History, and French and German. Manchester Grammar School.—£25 per annum, tenable for three years. The examinations for all these scholarships are held in the month of May. Kay-Shuttleworth (Sir James Phillips).—£30 per annum, tenable for three years. Subjects: Mathematics, Elementary Mechanics, Chemistry. Entrance Scholarships in Medicine.—One Scholarship in each year will be offered for proficiency in Arts and one for proficiency in Science. The Scholarships are of the value of £100 each, which will be set off against their fees as follows: £60 against the fees and £40 against the Infirmary fees. Platt Biological Scholarship.—£50 for one year, awarded to the candidate who shows the most promise and ability for prosecuting original research in Zoology and Botany. Dauntesey Medical Scholarships.—Two Scholarships of £35 each are open to all students preparing for a medical course who shall not have attended lectures or Laboratory courses on human anatomy or physiology, or a purely medical or surgical course in the University or any other Medical School in the United Kingdom. Candidates will be examined in Zoology, Botany, and Chemistry. Medals, are awarded on the results of the various class examinations at the end of each session. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the competition of persons whether previously students of the University or not. Two Platt Exhibitions, of the value of £15 each, to be competed for by first and second year students in the class of Physiology, and a Sidney Renshaw Exhibition in Physiology of the value of £15 to be competed for by second year students in Physiology. A Professor Tom Jones Memorial Exhibition of the value of £25, a Dumville Surgical Prize of £15, a Turner Medical Scholarship of £20, and a John Henry Agnew Scholarship in Diseases of Children of £30 are offered annually for competition. A Professor Tom Jones Memorial Scholarship of £100 is awarded triennially, a Bradley Memorial Scholarship in Clinical Surgery of the value of £20 and Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY (292 beds).—Consulting Physicians: Dr. Henry Simpson and Dr. J. Dreschfeld. Consulting Surgeons: Mr. Walter Whitehead and Mr. James Hardie. Physicians: Dr. Graham Steell, Dr. Thomas Harris, Dr. J. S. Bury, and Dr. A. T. Wilkinson. Assistant Physicians: Dr. Ernest S. Reynolds, Dr. R. T. Williamson, and Dr. E. M. Brockbank. Pathologist: Dr. J. Lorrain Smith. Consulting Obstetric Physician: Dr. Lloyd Roberts. Gynæcological Surgeon: Dr. Archibald Donald. Surgeons: Mr. F. A. Southam, Mr. G. A. Wright, Mr. William Thorburn, and Mr. J. E. Platt. Assistant Surgeons: Mr. W. P. Montgomery, Mr. J. W. Smith, Mr. A. H. Burgess, and Mr. J. H. Ray. Ophthalmic Surgeon: Dr. Hill Griffith. Aural Surgeon: Dr. William Milligan. Anæsthetist: Mr. Alex. Wilson. Consulting Dental Surgeon: Mr. G. W. Smith. Dental Surgeon: Mr. W. A. Hooton. Pathological Registrar: Dr. W. B. Anderton. Medical Registrar: Dr. A. Ramsbottom. Surgical Registrar: Mr. A. E. Johnson. Director of the Clinical Laboratory: Dr. E. B. Leech. Assistant Directors of the Clinical Laboratory: Dr. G. E. Loveday and Dr. A. Ramsbottom. Administrators of Anæsthetics: Mr. W. J. S. Bythell and Mr. A. F. Thompson. Assistant Medical Officer for Out-patients: Dr. W. R. Matthews. Assistant Surgical Officer for Out-patients: Mr. E. H. Cox. Medical Officer for Home Patients: Dr. George Ashton. General Superintendent and Secretary: Vacant. The Winter Session commences Oct. 1st.

THE ROYAL HOSPITAL, PORTSMOUTH (founded 1847).—The number of beds is 132. During the year 1905 there were 1414 in-patients and 11,583 out-patients. Honorary Physicians: Dr. John Phillips and Dr. O. C. Claremont. Surgeons: Dr. J. Ward Cousins, Dr. A. Lloyd Owen, and Mr. Henry Rundle, F.R.C.S. Honorary Anæsthetist: Dr. W. J. Essery. Honorary Assistant Physicians: Dr. W. P. McEldowney, Dr. L. Cole-Baker, and Dr. J. T. Leon. Honorary Assistant Surgeons: Mr. C. P. Childe, F.R.C.S., Mr. T. A. M. Forde, and Mr. A. B. Wright. The hospital is a preparatory School of Medicine and Surgery; the attendance of pupils at this hospital is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

UNIVERSITY OF SHEFFIELD.—FACULTY OF MEDICINE.—The Winter Session 1906–07 will commence in the new University buildings on Wednesday, Oct. 3rd. The University was opened on July 12th, 1905, by His Majesty King Edward VII. The plan of the buildings is that of four blocks inclosing a quadrangle 154 feet by 110 feet. The Medical department occupies the entire north wing, overlooking the quadrangle on one side and Weston Park on the other. The department of Anatomy occupies about two-thirds of the upper ground floor together with a portion of the lower ground floor, where the reception and storage room is situated. The dissecting room has been designed and equipped to meet all the modern requirements of the student of anatomy; it is well lighted by six large plate-glass windows and is floored with non-porous polished oak blocks. The lecture theatre will accommodate 50 students and is provided with a lantern of modern type illuminated by the electric arc. The anatomical museum has a gallery which is set apart for morphological and anthropological specimens. The floor space affords accommodation for bones, models, spirit specimens, and dissections. Research laboratories are provided for the professor and demonstrators. The Physiological department occupies the first floor. In the general laboratory, a large well-lighted room, accommodation is provided for microscopical work at a bench running the full length of the laboratory beneath the windows. The space behind is not occupied by the customary long fixed benches but by separate moveable tables, each equipped for the purposes of experimental work. This arrangement allows the students to work either singly or in small groups. The fixed equipment of the room is designed to provide power for machinery, gas, electricity, and water wherever the tables may be situated. The second laboratory, for chemical physiology, is fitted with benches, fume cupboards, &c. In addition, a considerable portion of this room is devoted to, and equipped for, work of a more advanced type. Opening into this laboratory are a balance room and two rooms fitted for photography, spectroscopy, &c. Opportunities are afforded for research work in three special rooms: one, beautifully lighted by windows in two of its walls, is equipped for general research; another, which can be darkened when required, for optical work and photographic recording; and a third, in the basement of the building, is provided with the solid pillars, &c., necessary for work with delicate instruments requiring great stability. In the lecture theatre a large amount of space has been left for the demonstration of experiments and is equipped with the larger pieces of apparatus necessary for such work. The Pathological department occupies the whole of the upper storey, and in this, as well as in the Anatomical and Physiological departments, no space is taken up by corridors, the plan being for the majority of the rooms to lead from one to the other. The students' laboratory, a large and lofty room, is equipped with every modern appliance for microscopical and bacteriological work. An incubating room, built into the centre of this department, is a special feature; it is so arranged that it may be kept at a constant temperature, thus replacing the ordinary incubating ovens. There is a spacious museum, with gallery, lighted from the roof and from windows on the south wall. The professor and demonstrators are provided with several research laboratories. The photographic and store rooms are situated in the roof and turrets. Well-furnished lecture rooms for other subjects and the materia medica museum are situated on the upper ground floor; and the library of the Medico-Chirurgical Society, to which students have access, is on the floor beneath, on the level of the quadrangle. Hospital practice, medical and surgical, is taken out at the Royal Infirmary and the Royal Hospital which are within easy distance of the University.

The Royal Infirmary contains 255 beds with special Ophthalmic, Dermatological, and Aural departments. The Royal Hospital contains 160 beds, including ophthalmic wards. There are also special out-patient departments for diseases of the skin, nose and ear, eye, throat, and mental diseases. At both these institutions clinical clerkships and dresserships, casualty and ophthalmic dresserships, and post-mortem clerkships are allotted each three months. Clinical lectures are delivered each week during the winter months by members of the staffs, and daily systematic teaching is given in the wards and out-patient rooms at stated times. By a joint arrangement students taking out hospital practice are able for the single fee to attend the practice of either or both of the institutions as they choose. Fees: Hospital practice, £36 15s. in one payment; or £18 18s. on commencing hospital practice and £18 18s. twelve months later. Composition fee for lectures and practical courses, £80, payable in three instalments—viz., £24, £28, £28. For practical midwifery and diseases of women students attend the Jessop Hospital for Women (80 beds), which has recently been considerably enlarged; for infectious diseases the City Fever Hospitals; and for mental diseases the South Yorks Asylum. Special courses are not included in the composition or hospital fees. In connexion with the University there is a complete dental department, which is fully recognised by the various examining bodies, and students are able to get their full curriculum here. The practical work is done at the dental department of the Sheffield Royal Hospital, where, in addition to the fully-equipped out-patient dental rooms, there is a very complete practical dental mechanical room and laboratory fitted with electric light and every modern convenience. Each student has his own bench and fittings provided. The courses of instruction for the D.P.H. examinations are recognised by the Royal College of Surgeons, Cambridge University, and the University of London. Persons of either sex are admitted to the degree of the University.

Prizes, &c.—An entrance scholarship of the approximate value of £100 is awarded on the results of the Matriculation Examination of the Joint Matriculation Board held in July. A gold medal for Clinical Medicine and Surgery is offered by the Clinical Committee. Kaye Scholarship (being the interest on £900) for second-year students natives of Sheffield is awarded annually under certain regulations. Medals and certificates are awarded annually.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—The hospital contains 54 beds for gynæcological cases and 18 for obstetric cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and, in case of need, are assisted by the members of the medical staff. A 12 weeks' course of instruction (theoretical and practical) is also provided for resident and non-resident pupil midwives, the institution being approved by the Central Midwives Board as a training centre. Out-patients are attended daily. Students can attend the practice of the hospital and be supplied with cases of midwifery. Communications should be addressed to the Secretary, A. W. Warner, York Chambers, York-street, Sheffield.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Dr. H. Davy and Dr. William Gordon. Surgeons: Mr. J. D. Harris, Mr. E. J. Domville, Mr. Charles E. Bell, and Mr. A. C. Roper. Medical Registrar and Pathologist: Mr. Reginald V. Solly. Surgeon Dentist: Mr. J. M. Ackland. Anæsthetists: Mr. Henry Andrew and Mr. Brennan Dyball The hospital contains 200 beds (*including special children's wards*) and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery on application to the House Surgeon. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c, apply to the Matron. A new wing was added in 1897. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon).

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Honorary Consulting Physician: Dr. R. Saundby. Honorary Consulting Surgeon: Mr D C. Lloyd-Owen. Surgeons: Mr. H. Eales, Mr. E. W. Wood-White, and Mr. J. Jameson Evans. Dental Surgeon: W. T. Madin, L.D.S. Anæsthetist: Dr. S. W. Haynes. This hospital possesses 105 beds, and there is an average daily attendance of out-patients of 205. This institution is recognised by Universities and the Royal College of Surgeons, England, and Royal College of Physicians, London, as an ophthalmic hospital at which clinical instruction in ophthalmology may be received. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations.

WEST OF ENGLAND EYE INFIRMARY, Exeter —Physician: Dr. William Gordon Surgical Staff: Mr. A. C. Roper and Mr. Ransom Pickard. Assistant Surgeon: Mr. Leonard R. Tosswill. Secretary: Mr. Sidney E. Whitton. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1905, 2757.

KENT AND CANTERBURY GENERAL HOSPITAL.—The hospital contains 104 beds. Pupils of the staff are admitted to the practice of the hospital and have the use of the library of the East Kent and Canterbury Medical Society for £7 7*s.* Operation day, Thursday, 11 A.M. Physicians: Dr. Harold Wacher and Dr. M. T. Williams. Consulting Surgeons: Mr. James Reid and Mr. Frank Wacher. Surgeons: Dr. T. Whitehead Reid, Mr. J. Greasley, Mr. Sidney Wacher, and Mr. Z. Prentice. Dentist: Mr. R. S. N. Faro. Secretary: Mr. Arthur J. Lancaster. Over 700 in-patients, 2000 out-patients and casualties, and 400 dental cases are attended in a year.

NORFOLK AND NORWICH HOSPITAL (220 beds).—Non-resident pupils admitted. Fees: For three months, £3 3*s.*; for six months, £5 5*s.*; as permanent pupil, £8 8*s.* Consulting Physician: Sir P. Eade. Consulting Surgeons: Dr. Beverley, Mr. H. S. Robinson, and Mr. O. Williams. Physicians: Dr. Barton, Dr. Burton-Fanning, and Dr. Long. Surgeons: Mr. S. H. Burton, Mr. D. D. Day, and Mr. H. A. Ballance. Assistant Surgeons: Mr. T. H. Morse and Mr. E. W. Everett. Dental Surgeon: Mr. H. F. White. Electro-Therapeutist: Dr. A. J. Cleveland. Secretary: Mr. F. G. Hazell.

NORTHAMPTON GENERAL HOSPITAL (established 1743; rebuilt 1793).—Two new wings were opened in 1904 and the old buildings entirely renovated and re-arranged. The number of beds is 166. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10*s.* Pupils can be received at any time.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan. has accommodation for over 200 patients, including Children's wards, special Ovarian wards, and a special department for the treatment of Diseases of the Eye. In-patients last year, 2162; out-patients, 13,920. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians: Dr. H. Nicholls and Dr. S. King Alcock. Surgeons: Dr. G. Stokes Hatton and Dr. Wheelton Hind. Assistant Physician: Mr. John Russell. Assistant Surgeons: Mr. Reginald Alcock and Dr. W. C. Allardice. Ophthalmic Surgeon: Mr. Herbert H. Folker. Assistant Ophthalmic Surgeon: Mr. R. H. Dickson. Dental Surgeon: Mr. A. Baines. Secretary and House Governor: Mr. Albert E. Boyce, F.C.I.S., A L C.A.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—There are 230 beds. It is recognised by the University of London, the Royal Colleges of Physicians and Surgeons, and other examining boards. The in-patients number 2550; the out-patients 19,985. The Operating Theatre, Pathological Laboratory, and Post-mortem room are new and well equipped. Special departments for Children, Gynæcology, Ear, Throat, and Nose Diseases, Electro-therapeutic and X Ray departments. There is an excellent library. The resident officers are a house physician, house surgeon, assistant house physician, and assistant house surgeon. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a practical knowledge of their profession. Fees: £3 3*s.* a quarter, £10 10*s.* the first year, and £5 5*s.* subsequent years. A course of Practical Pharmacy is given by the dispenser. Fee £3 3*s.* for three months. Applications should be made to the Secretary of the Medical Committee Staff.

Staff.—Consulting Physician: Dr. W. Millington. Consulting Surgeon: Mr. C. A. Newnham. Physicians: Dr. H. Malet and Dr. C. A. MacMunn. Surgeons: Mr. J. O'B. Kough, Mr. W. H. T. Winter, Mr. E. Deanesly, and Mr. A. H. Hunt. Assistant Physician: Dr. J. A. Codd. Assistant Surgeons: Mr. W. F. Cholmeley and Mr. H. Dent.

SUSSEX COUNTY HOSPITAL (190 beds).—During the year 1905, 2145 in-patients have been treated. The total number of out-patient attendances on the books during 1905 was 39,625. This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Committee of Management shall direct.

Staff.—Consulting Physicians: Dr. Rutter, Dr. Hollis, Dr. Branfoot, and Dr. Mackey. Physicians: Dr. F. F. G. Dill, Dr. Hobhouse, and Dr. Maynard. Assistant Physicians: Dr. W. Broadbent, Dr. Hall, and Dr. Bailey. Consulting Surgeons: Mr. F. A. Humphry and Mr. H. P. Blaker. Surgeons: Mr. W. Furner, Mr. T. J. Verrall, and Mr. R. F. Jowers. Assistant Surgeons: Mr. F. J. Paley, Mr. A. Buck, and Mr. T. H. Ionides.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury and Gartside-street, Manchester.—The hospital contains 168 beds and 24 in the Convalescent Home, St. Anne's-on-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the Dispensary, Gartside-street, Manchester. Physicians: Dr. Ashby, Dr. Hutton, and Dr. Heywood. Surgeons: Mr. J. Howson Ray, Mr. E. D. Telford, and Mr. C. Roberts *Honorary Consulting Surgeon: Mr G. A. Wright. Honorary* Consulting Pathologist: Professor R. Lorrain Smith. Anæsthetist: Mr. Harold Snape. Honorary Aural Surgeon: Mr. F. H. Westmacott. Pathologist: Dr. W. Mair. Honorary Dental Surgeon: Mr. Barron J. Rodway. Resident *Medical Officers*: Mr. J. L. Falconer and Mr. R. T. Slinger. Medical Officers at the Dispensary: Dr. C. P. Lapage and Mr. H. H. Rayner. During 1905 there were 1910 in-patients and 23,899 out-patients were under treat ment at the Dispensary. Secretary: Mr. H. J. Eason.

THE MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park place, Cheetham-hill-road, Manchester.—The hospital contains 70 beds. Out-patients are seen daily from 8.30 to 10 A.M. Honorary Consulting Physicians: Dr. W. N. Maccall, Dr. S. Holgate Owen, and Dr. T. C. Railton. Honorary Consulting Surgeons· Mr. James Hardie and Mr. Frederick A. Southam. Honorary Physician for Women: Dr. Samuel Buckley. Honorary Surgeon for Women: Mr. T. Arthur Helme. Honorary Surgeon for Children: Mr. Arnold W. W. Lea. *Honorary Physician: Dr. J. J. Cox.* Honorary Assistant *Physician*: Dr. W. E. Fothergill. Honorary Assistant Physicians for Children: Dr. C. H. Melland and Dr. C. C. Heywood. Honorary Assistant Surgeon for Children: Mr. Charles Roberts. Honorary Anæsthetists: Mr. G. A. Barrow and Dr. H. R Clarke. Pathologist: Dr. J. Garvie McNaughton. Assistant Medical Officers: Dr. A. W. Lilley and Mr. R. W. Walsh. Honorary Dentist: Mr. W. A. Hooton. House Surgeon: Mr J. Bowen Jones.

NEWCASTLE-ON-TYNE INFIRMARY FOR DISEASES OF THE EYE.—Staff Surgeons: Mr. A. S. Percival and Mr. H. P. Bennett. Assistant Surgeons: Mr. Andrew Messer and Mr. W. J. Penfold. Honorary Consulting Surgeon: Mr. Frederick Page. Honorary Anæsthetists: Dr. O. W. Ogden and Mr. T. H. Livingstone. Matron: Miss C. Crump. Secretary: Mr. Richard Smith, 61, Westgate-road, Newcastle-on-Tyne. Out-patients 6085 annually; in-patients 335. Instruction is given daily from 11 to 1.

LEICESTER INFIRMARY.—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 158 beds and at the Children's Hospital 42; total 200.

SCOTLAND.

MEDICAL SCHOOLS WITH FULL CURRICULUM.[1]

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1200 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards. A post graduate vacation course commences in the last fortnight of September.

The anatomy rooms and laboratories will open on Monday, Oct. 1st. On Tuesday, Oct. 16th, the lectures will commence.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school, in addition to the class of Practical Materia Medica and the classes of Clinical Medicine and Clinical Surgery. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

The appointment of Resident Physician to the wards in the Royal Infirmary under the care of the Ordinary Physicians is open to those members of their clinical class who have held the office of clerk in their wards for at least six months. Six Residentships are appointed for a period of six months each. Resident Surgeons are also appointed by the Ordinary Surgeons to the Hospital. In all respects the students are taught under regulations similar to those at the University of Edinburgh and the other Universities of Scotland, and they receive similar certificates at the close of each session. Moreover, the University and College authorities in Edinburgh and the governing board of the school call upon each recognised lecturer to supply them at the close of each session with a statement giving the number of students attending the class, the number of lectures or prelections delivered during the session, the class examinations held, and the general mode of conducting the class. The courses on special non-qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra-murally. A list of the classes and lecturers will be found below. Special courses of instruction for dental students and for women are also included in the curriculum of this school. The classes of the school are conducted in several separate buildings, such as at Surgeons' Hall, Minto House, Nicolson-square, and the New School, Bristo-street.

Lecturers and fees.—Winter Session: Anatomy, Practical Anatomy, and Demonstrations, Dr. Ryland Whitaker (£3 5*s.* and £4 4*s.*); Chemistry (Practical, &c.), Mr. King, Mr. Gemmell, Mr. Kerr,* and Dr. T. W. Drinkwater; Physiology (Institutes of Medicine) —— (£3 5*s.*); General Pathology, &c., Dr. Russell, Dr. Shennan, and Dr. Stuart McDonald (£3 5*s.*); Biology, Mr. Malcolm Laurie (£3 5*s.*); Zoology, Mr. Malcolm Laurie; *Physics, Dr. Dawson Turner (£3 3s.); Bacteriology*, Dr. Taylor Grant, Dr. Theodore Shennan, and Dr. Stuart McDonald; Practice of Physic, Dr. James, Dr. Bramwell, Dr. Gibson, Dr. Bruce, Dr. Philip, and Dr. R. A. Fleming (£3 5*s.*); Surgery, Mr. Caird, Mr. Hodsdon, Mr. Thomson, Mr. Wallace, Mr. Miles, and Mr. Scot Skirving (£3 5*s.*); Materia Medica, &c., Dr. Craig† and Dr. F. D. Boyd (£3 5*s.*); Midwifery, &c., Dr. Hart, Dr. Haultain, Dr. Ballantyne, Dr. Fordyce, Dr. Elsie M. Inglis, and Dr. Campbell (£3 5*s.*); Medical Jurisprudence, &c., Dr. Aitchison Robertson (£3 5*s.*); Public Health, Dr. Aitchison Robertson and Dr. C. J. Lewis; Hospital Practice (Edinburgh Royal Infirmary): Physicians, Dr. James, Dr. Bramwell, Dr. Gibson, and Mr. Brewis for Gynæcology; Surgeons, Dr. MacGillivray, Mr. Cotterill, and Mr. Cathcart (perpetual ticket, £12); Clinical Medicine, Dr. James, Dr. Byrom Bramwell, and Dr. Gibson (£3 5*s.*); Clinical Surgery, Dr. MacGillivray, Mr. Cotterill, and Mr. Cathcart (£3 5*s.*); Diseases of the Chest, Dr. Philip† and Dr. Lovell Gulland (£2 2*s.*); Vaccination, Dr. Buist† and Dr. Cadell (£1 1*s.*); Diseases of Ear, Nose, and Throat, Dr. Logan Turner and Dr. J. Malcolm Farquharson (£2 2*s.*); *Diseases of the Eye, Dr. Sym,*† and Dr. A. H. H. Sinclair (£2 2*s.*); Gynæcology, Dr. Haig Ferguson and Dr. Elsie M. Inglis (Systematic), Dr. Brewis, and Dr. J. Haig Ferguson (Clinical), and Dr. *Berry Hart (Advanced)* (£2 2*s.*); Diseases of the Blood, Dr. G. Lovell Gulland; Neurology, Dr. J. J. Graham Brown (£2 2*s.*); Diseases of the Chest, Dr. Philip and Dr. Lovell Gulland *(£2 2s.)*; *Medical* Electricity, Dr. Dawson Turner (£2 12*s.* 6*d.*); Tropical Diseases, Major D. G. Marshall, I.M.S. (£2 2*s.*). Summer Session: Practical Anatomy and Demonstrations, Dr. Ryland Whitaker (£2 2*s.*); Practical Physiology —— (£3 3*s.*); *Biology, Mr. M. Laurie ‡ and Miss Newbigin (£3 3s.)*; Practical Chemistry and Analytical Chemistry, Mr. King, Mr. Gemmell, Mr. Kerr, and Mr. Drinkwater §; Practical *Bacteriology*, Dr. *Shennan*, Dr. Taylor Grant, and Dr. Stuart McDonald; Materia Medica, Dr. Craig and Dr. F. D. Boyd; Diseases of the Eye, Dr. Sym and Dr. A. H. H. Sinclair (£2 2*s.*); Medical *Psychology* and Insanity, Sir J. Batty Tuke and Dr. Robertson (£2 2*s.*); Medical Jurisprudence, Dr. Aitchison Robertson; Public Health, Dr. C. J. Lewis *(£2 2s.)*; *Gynæcology, Dr.* Brewis and Dr. Ballantyne (£2 2*s.*); Midwifery, Dr. Ferguson, Dr. Ballantyne, Dr. Fordyce, Dr. Elsie M. Inglis, and Dr. Campbell (£3 5*s.*); Operative Surgery, Mr. *Caird*, Mr. Hodsdon, Mr. Alexis Thomson, Mr. David Wallace, and Mr. Alex. Miles (£3 3*s.*); Practical Pathology, Dr. Russell, Dr. Shennan, and Dr. Stuart McDonald (£3 3*s.*); *Physics*, Dr. Turner‡ (£3 3*s.*); Practical Medicine and Physical Diagnosis, Dr. Philip, Dr. Fleming, and Dr. Lovell Gulland (£3 3*s.*); Practice of Medicine, Dr. James, Dr. Bramwell, and Dr. Gibson (£2 2s.); Vaccination, Dr. Buist and Dr. Cadell (£1 1s.); Neurology, Dr. Bruce and Dr. Graham Brown; Diseases of Ear, Nose, and Throat, Dr. Logan Turner and Dr. Malcolm Farquharson (£2 2s.); Tropical Diseases, Major D. G. Marshall, I.M.S. (£2 2s.); Medical Electricity, Dr. Dawson Turner.

---

[1] For Scholarships see p. 601 et seq.

Special Classes for Women, Winter Session: Practical Anatomy and Demonstrations, Dr. Ryland Whitaker (£4 4s.); Chemistry (Lectures and Practical), Mr. J. Kerr (£3 5s. and £3 3s.); Practice of Physic, Dr. Philip (£3 5s.); Surgery, Mr. J. W. Dowden (£3 5s.); *General Pathology*, Dr. Russell (£3 5s.); Physiology (Institutes of Medicine) —— (£3 5s.); Materia Medica, &c., Dr. Craig (£3 5s.); Clinical Medicine, Dr. Alexander Bruce, Royal Infirmary (£3 5s.); Clinical Surgery, Mr. Caird, Royal Infirmary (£3 5s.); Physics, Dr. Dawson Turner (£3 3s.); Biology, Miss Newbigin (£3 3s.); Vaccination, Dr. Buist and Mr. Cadell (£1 1s.); Practical Gynæcology, Dr. Brewis (£2 2s.); Diseases of the Eye, Dr. W. G. Sym; Bacteriology, Dr. J. Taylor Grant; Fevers, City Hospital. Summer Session: Practical Anatomy, Dr. Ryland Whitaker (£2 2s.); Practical Chemistry, Mr. J. Kerr (£3 3s.); Materia Medica, &c., Dr. Craig (£3 3s.); Operative Surgery and Surgical Anatomy, Mr. J. W. Dowden (£3 3s.); Materia Medica and Therapeutics, Dr. Wm. Craig (£3 3s.); Medical Jurisprudence and Public Health, Dr. Aitchison Robertson and Dr. C. J. Lewis (£3 5s.); Clinical Medicine, Dr. Alexander Bruce; Clinical Surgery, Mr. Caird, Royal Infirmary (£3 5s.); Practical Physiology and Histology —— (£3 3s.); Practical Pathology, Dr. Russell (£3 3s.); Biology, Miss Newbigin (£3 3s.); Physics, Dr. Dawson Turner (£3 3s.); Ophthalmology, Dr. A. H. H. Sinclair (£2 2s.); Insanity, Sir J. Batty Tuke and Dr. G. M. Robertson (£2 2s.); Practical Gynæcology, Dr. Brewis (£2 2s.); Practical Medicine, Dr. Philip and Dr. G. Lovell Gulland; Vaccination, Dr. Buist; Tropical Diseases, Major Marshall; Medical Electricity, Dr. Dawson Turner.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £115, payment of which is distributed over the period of study.

Further particulars regarding the school, also its calendar, may be had on application to Mr. R. N. Ramsay, the Secretary and Registrar, 27, Forrest-road, Edinburgh.

* Lectures, £3 5s.; Practical, £3 3s.; Analytical, £2 a month, or £5 for three months. † Also in Summer Session. ‡ Also in Winter Session. § Practical, £3 3s.; Analytical, £2 a month, or £5 for three months.

N.B.—Where two or more lecturers appear as teaching the same subjects their lectures are not conjoined, but each gives an independent course.

ANDERSON'S COLLEGE MEDICAL SCHOOL, Dumbarton-road, Glasgow.—This medical school was founded in the year 1800. It has given 15 *professors* to the University of Glasgow. The following courses are given, which qualify for all the licensing boards and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions):—In winter: Anatomy, Professor A. M. Buchanan; Chemistry, Professor J. Robertson Watson; Physics, Professor Peter Bennett; Botany, Professor B. G. Cormack; Zoology, Professor Geo. Bell Todd; Physiology: Professor Robert Fullarton; Materia Medica, Professor Hugh M'Laren; Midwifery, Professor John Edgar; Surgery, Professor J. H. Nicoll; Practice of Medicine, Professor R. Barclay Ness; Ophthalmic Medicine and Surgery, Dr. T. Spence Meighan; Aural Surgery, Dr. J. Galbraith Connal; Diseases of Throat and Nose, Dr. John Macintyre; Public Health (Laboratory Course), Professor Carstairs C. Douglas. In summer: Anatomy, Practical Anatomy, and Osteology; Practical Chemistry; Botany and Practical Botany; Zoology and Practical Zoology; Practical Physiology; Practical Materia Medica and Pharmacy; Medical Jurisprudence and Hygiene (Professor Carstairs C. Douglas); Diseases of Women and Children (Professor Edgar); Operative Surgery; Ophthalmic Medicine and Surgery; Aural Surgery; Mental Diseases (Dr. John Carswell); and Public Health (Lecture Course). The Chemical Laboratory is open daily from 10 to 6. The Dissecting-room is open in winter from 9 A.M. to 6 P.M., and in summer from 6 A.M. to 6 P.M. The students are assisted in their dissections by the Professor and Demonstrators, by whom frequent examinations and demonstrations on the parts dissected are conducted. The supply of subjects for dissection is ample, and students are consequently provided with parts as soon as they may be ready for them. The Dissecting-room is provided with a complete series of dissected specimens, mounted in plaster of Paris, illustrating the anatomy of the human body. Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Glasgow Dental Hospital and School.

The new buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, within two minutes' walk of it, and four minutes' walk of the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Physiology, Practical Pharmacy, and Operative Surgery. There are also provided a large reading-room and students' recreation-room.

Fees.—For each course of Lectures (Anatomy, Ophthalmic Medicine and Surgery, Aural Surgery, Diseases of Throat and Nose, and Mental Diseases and Public Health excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s.; afterwards free. For Practical Classes (except Anatomy, Operative Surgery, and Public Health)—viz., Chemistry, Botany, Zoology, Physiology, and Pharmacy—first session, £2 2s.; second session, £2 2s. Reduced joint fees in Zoology and in Botany, for Lectures and Practical Class when taken in same summer session, £3 3s.; for either course separately, £2 2s. Anatomy Class Fees: Winter, first session (including Practical Anatomy), £4 4s.; second session (including Practical Anatomy), £4 4s.; third session, £2 2s. Summer, Lectures and Practical Anatomy, £2 12s. 6d.; Lectures alone, £1 11s. 6d.; Practical Anatomy *alone*, £1 11s. 6d.; Osteology and Practical Anatomy, £2 12s. 6d.; Osteology alone, £1 11s. 6d.; Operative Surgery, £2 12s. 6d. Ophthalmic Medicine and Surgery (including Hospital Practice), Aural Surgery, Diseases of Throat and Nose, and Mental Diseases, £1 1s. each course. Public Health Laboratory, six months, £11 11s.; with lectures, £12 12s. Matriculation Fees: For the year, 10s.; for one class in winter session alone, 5s.; for summer session alone, 5s.

Western Infirmary.—Fees: For Hospital Attendance, £10 10s.; afterwards free. For Clinical Instruction, winter, £3 3s.; summer, £2 2s. Pathology: systematic, £4 4s.; practical, £3 3s. Vaccination fee, £1 1s.

Royal Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s. Pathology, both courses, £4 4s. Vaccination Fee, £1 1s.

Attendance at the dispensaries of the Western and Royal Infirmaries is included in the *hospital fee.*

Maternity Hospital.—Fee for six months, £3 3s.

Royal Hospital for Sick Children.—Fee for one year, £1 1s.

Eye Infirmary.—Fee: Hospital Practice and Clinical instruction, including Lectures at the College, six months, £1 1s.

Lock Hospital.—£1 1s.

Fever Hospital, Belvidere or Ruchill.—Fee, £1 1s.

Hospital for Skin Diseases.—Fee, £1 1s.

The Carnegie Trust extends its benefactions to students at Anderson's College Medical School. Full particulars may be obtained from Mr. W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Certificates of attendance on the lectures at Anderson's College Medical School are received by the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions); by the Royal Colleges of Physicians of London and Edinburgh; by the Royal Colleges of Surgeons, England, Edinburgh, and Ireland; by the Royal College of Physicians of Ireland; by the Faculty of Physicians and Surgeons of Glasgow; by the Society of Apothecaries, London; and by the Army, Navy, and East India Boards. The courses of Laboratory Instruction and Lectures in Public Health are recognised by the Scottish Colleges; by the Royal College of Physicians and the Royal College of Surgeons, Ireland; and by the University of Cambridge. Communications relating to the Medical School to be addressed to the Secretary of the Medical Faculty, Anderson's College Medical School, Dumbarton-road, Partick, Glasgow. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Alexander Mackay, Educational Institute Office, 40, Princes-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Alexander Duncan, LL.D., Faculty Hall, 242, St. Vincent-street, Glasgow. Communications relating to the Dental School to be addressed to Mr. D. M. Alexander, 97, West Regent-street, Glasgow.

The *Kerr Bursary in Anatomy* (value about £10) is open to students of the Junior Anatomy Class during Winter Session 1906-1907.

The Winter Session will be opened on Thursday, Oct. 18th, 1906, and will be closed on Thursday, March 28th, 1907.

The Summer Session will be opened on Wednesday, April 24th, 1907, and will be closed on Friday, July 5th, 1907.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—This College was incorporated in 1889. The Glasgow Royal Infirmary was founded in 1791. The Faculty of Medicine of the College occupies new buildings erected for the purposes of a medical school, adjoining and communicating with the Royal Infirmary. The Laboratories, Museums, and Lecture-rooms are equipped and adapted to modern scientific requirements. Recent additions consist of Public Health, Practical Zoology, and Bacteriological Laboratories. A complete electric light installation has been added and a powerful Educational Lantern has been provided for demonstration purposes. The Royal Infirmary, which is at the service of the College for the purpose of clinical and practical instruction, is one of the largest hospitals in the kingdom. The winter session will open on Thursday, Oct. 18th.

Psychological Medicine.—Practical instruction is given in Woodilee Asylum, situated within a short distance of Glasgow and having accommodation for 850 patients. Six resident clinical clerks are appointed annually. These clerkships are open to students attending St. Mungo's College.

Clinical Instruction in Fevers.—Classes are conducted by Dr. Johnston, Superintendent, at the City of Glasgow Fever Hospital, Ruchill, and Dr. Brownlee, Superintendent, at the City of Glasgow Fever Hospital, Belvidere.

Clinical Instruction in Midwifery.—The close proximity of the Maternity Hospital enables the Professor of Midwifery to conduct frequent clinical demonstrations there during the summer session.

The classes in St. Mungo's College qualify for the English, Scotch, and Irish Conjoint Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College.

The fee for each class is £2 2*s.*, except Zoology and Botany, joint fee £3 3*s.*, Anatomy, Winter Session, £4 4*s.*, Pathology, £4 4*s.*, Physics, £2 4*s.* 6*d.*, and certain extra classes for which the fee is £1 1*s.* The hospital fee (including clinical lectures) is £21 for a perpetual ticket. The classes in St. Mungo's College and in the Glasgow Royal Infirmary are for male students exclusively. The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons amount to £65. Further particulars can be obtained from a syllabus which can be obtained free on application to the Dean, 86, Castle-street, Glasgow.

GLASGOW WESTERN MEDICAL SCHOOL.—This School is situated in University-avenue, close to the University and Western Infirmary. Lectures and Demonstrations are given on Chemistry, on Physics, on Anatomy, on Surgery, on Physiology, on Midwifery and Gynæcology, on Pathology, on Medicine, and on the Eye.

Class Fees.—For each course of Lectures the fee is £2 2*s.*, or in some cases £1 1*s.* There is no matriculation fee.

Lecturers: Winter Session.—Physics: Dr. Muirhead, Monday, Wednesday, and Friday, at 2 P.M.; Chemistry: Tuesday and Thursday, at 3 P.M.; Anatomy: Dr. Wright Thomson, Tuesday, Wednesday, and Friday, at 4.15 P.M.; Surgery: Dr. Edington, at 12 noon; Midwifery: Dr. Balfour Marshall, Monday, Wednesday, and Friday, at 2 P.M.; Medicine: Dr. Cowan, at 11 A.M.; Pathology: Dr. McLaren, Monday, Tuesday, Thursday, and Friday, at 3 P.M.; The Eye: Dr. Fergus, Monday and Thursday, at 4 P.M.

Summer Session.—Physics: Dr. Muirhead, Monday, Wednesday, and Friday, at 2 P.M.; Chemistry: Tuesday and Thursday, at 3 P.M.; Anatomy: Dr. Wright Thomson, Tuesday and Friday, at 3.15 P.M.; Operative Surgery: Dr. Edington, Tuesday, Wednesday, and Friday, at 1 P.M.; Gynæcology: Dr. Balfour Marshall, at 2 P.M.; Medicine: Dr. Cowan, at 8 A.M.; Pathology: Dr. McLaren, Monday, Tuesday, Thursday, and Friday, at 12 noon; Ophthalmology: Dr. Fergus, Monday and Thursday, at 11 A.M. and 3 P.M. Some of these classes qualify for graduation and for Scotch diplomas.

QUEEN MARGARET COLLEGE, University of Glasgow.—Queen Margaret College was founded in 1883 by the Glasgow Association for the Higher Education of Women (instituted in 1877), and handsome buildings and grounds near the University were presented to the College in 1884 by Mrs. John Elder. In 1890 a School of Medicine for women was added to its Arts Faculty. In 1892, when the Universities Commissioners issued an ordinance empowering the Scottish University Courts to make provision for the instruction of women, the Council of the College and Mrs. Elder transferred to the University the College, its buildings, grounds, and endowments, on condition that these should be devoted to the maintenance of University classes for women only. The College then became the women's department of the University of Glasgow; its classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The number of students enrolled in session 1905-1906 was 502, of whom 70 were studying medicine and the rest arts or science. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish university, women students graduated in medicine at the "capping" in Glasgow University. 117 women have now taken the degree of M.B., C.M. or M.B., Ch.B. of the University of Glasgow. Excellent facilities for clinical work are given in the Royal Infirmary and other hospitals. By a gift of £5000 granted for the purpose by the Bellahouston Trust the University Court was enabled to add to the College a large building for the study of Anatomy and Physiology, which was opened in October, 1895. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. A house of residence for the students of the College coming from a distance was opened by the Queen Margaret Hall Co., Limited, in October of 1894. The winter session commences on Oct. 18th.

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. The new medical buildings, containing laboratories and workrooms for Anatomy, Physiology, Materia Medica, Pathology, Ophthalmology, Public Health, Medicine, Surgery, and Gynæcology will be opened in October. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

ROYAL INFIRMARY, Dundee.—The Infirmary contains 300 beds, including special wards for the Diseases of Women, Children, Eye, Ear and Throat, and Obstetric cases. There is in addition an Extern Obstetric Department. There were during last year 15,549 out-patients and 6411 home patients. The Royal Infirmary offers exceptional facilities for practical work to students. *Appointments*: Four qualified Resident Medical Assistants are appointed every six months and one non-resident. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica and in Practical Dentistry. Further information can be obtained from Dr. Fraser, Medical Superintendent.

ROYAL AND DISTRICT ASYLUMS, Dundee.—Physician

Superintendent: Dr. William Tuach-Mackenzie. Lectures on Mental Diseases and clinical instruction in connexion with University College, Dundee (University of St. Andrews), are given during the Summer Session at University College and at the Royal and District Asylums by Dr. Tuach-Mackenzie. The course consists of 12 Lectures and 14 Clinical Lectures and Demonstrations. There are two paid qualified Resident Assistants and two unpaid Resident Clinical Assistants. Senior Medical Assistant: Dr. H. C. Martin. Junior Medical Assistant: Dr. J. Morris. Clinical Assistants: Mr. D. Buist and Mr. J. Robertson.

Aberdeen Royal Lunatic Asylum.—Contains, with hospital attached to main institution and Agricultural Branch, about 936 beds. Medical Superintendent: Dr. William Reid. Assistant Physicians: Dr. H. de M. Alexander, Dr. Reg. A. Forster, and Mr. John H. Moir. Clerk, Treasurer, and Factor: Mr. A. Scott Finnie, 343, Union-street, Aberdeen. Clinical instruction is given to students during three months in summer.

Aberdeen Royal Infirmary.—Contains 251 beds. Consulting Physician: Dr. P. Blaikie Smith. Physicians: Dr. Angus Fraser, Professor Finlay, and Dr. George M. Edmond. Assistant Physicians: Dr. John Gordon, Dr. A. H. Lister, and Dr. Ashley W. Mackintosh. Consulting Surgeons: Professor Alexander Ogston, Dr. J. C. O. Will, and Dr. J. Mackenzie Booth. Surgeons: Mr. J. S. Riddell, Mr. John Marnoch, and Mr. H. M. W. Gray. Assistant Surgeons: Dr. Kelly, Dr. Henry Peterkin, and Dr. Thomas S. Slessor. Ophthalmic Surgeon: Dr. C. H. Usher. Gynæcologist: Professor W. Stephenson. Pathologist: Professor David James Hamilton. Assistant Pathologist: Dr. G. M. Duncan. Dental Surgeon: Dr. J. M. P. Crombie. Anæsthetist: Dr. J. J. Y. Dalgarno. Assistant Anæsthetists: Dr. W. R. Pirie and Dr. Thos. Fraser. Medical Electrician: Dr. J. R. Levack. Assistant Medical Electrician: Dr. Clifford T. Bell. Dermatologist and Lecturer on Diseases of the Skin: Dr. J. F. Christie. Medical Superintendent and Clinical Registrar: Dr. William Sinclair. Clerk and Treasurer and Factor for the Hospital Lands: Mr A. Scott Finnie, 343, Union-street, Aberdeen. Medical session open on Oct. 16th.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

Royal Infirmary, Edinburgh.—This hospital has 900 beds and 60 cots for children, the average daily number of patients for 1905 being 828. Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There is a large and complete Medical Electrical and X Ray Department. Three wards are specially set apart for Clinical Instruction to Women Students. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*: six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student to a life ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

Staff: Medical Department.—Consulting Physicians: Dr. Claud Muirhead and Dr. J. O. Affleck. Consulting Gynæcologists: Sir J. Halliday Croom and Emeritus Professor Sir A. R. Simpson. Professors of Clinical Medicine: Sir T. R. Fraser, Dr. W. S. Greenfield, and Dr. John Wyllie. Ordinary Physicians and Lecturers on Clinical Medicine: Dr. Alex. James, Dr. Byrom Bramwell, Dr. Geo. Gibson, Dr. Alex. Bruce, and Dr. R. W. Philip. Gynæcologists: Dr. A. H. F. Barbour and Mr. N. T. Brewis. Physician for Disease of the Skin: Dr. Norman Walker. Medical Electrician: Dr. Dawson Turner. Assistant Physicians: Dr. William Russell, Dr. Murdoch Brown, Dr. G. Lovell Gulland, Dr. J. J. Graham Brown, Dr. Francis D. Boyd, and Dr. R. A. Fleming (*one vacancy*). Assistant Gynæcologists: Dr. F. W. N. Haultain, Dr. J. Haig Ferguson, and Dr. Wm. Fordyce. Assistant Physicians for Diseases of the Skin: Dr. Fred. Gardiner (*one vacancy*). Assistant Medical Electrician: Dr. Hope Fowler. Medical Registrar: Dr. A. Dingwall Fordyce.

Surgical Department.—Consulting Surgeons: Sir P. H. Watson, Mr. Joseph Bell, Mr. A. G. Miller, and Dr. P. H. Maclaren. Consulting Dental Surgeon: Dr. John Smith. Consulting Ophthalmic Surgeons: Dr. Argyll Robertson and Mr. George A. Berry. Consulting Aural Surgeon: Dr. P. McBride. Consulting Surgeon for Diseases of the Ear and Throat: Dr. R. McKenzie Johnston. Regius Professor of Clinical Surgery: Mr. Annandale. Professor of Surgery: Mr. Chiene. Ordinary Surgeons: Dr. C. W. MacGillivray, Mr. J. M. Cotterill, Mr. C. W. Cathcart, and Mr. F. M. Caird. Ophthalmic Surgeons: Dr. George Mackay and Dr. Wm. G. Sym. Surgeon to Ear and Throat Department: Dr. A. Logan Turner. Dental Surgeons: Mr. William Guy and Mr. J. H. Gibbs. Assistant Surgeons: Mr. Hodsdon, Mr. D. Wallace, Mr. Alexis Thomson, Mr. Alexander Miles, Mr. J. W. Dowden, Mr. A. A. Scot Skirving, and Mr. Geo. L. Chiene. Assistant Ophthalmic Surgeons: Dr. J. V. Paterson and Dr. A. H. H. Sinclair. Assistant Surgeons to the Ear and Throat Department: Dr. J. Malcolm Farquharson (*one vacancy*). Pathologist: Dr. Theodore Shennan. Assistant Pathologists: Dr. W. T. Ritchie (Clinical Pathology), and Dr. Henry Wade and Dr. Carnegie Dickson (Morbid Anatomy). Surgical Registrar: Dr. Scott Carmichael. Superintendent: Colonel W. P. Warburton, I.M.S. (retired), M.D., C.S.I.

Royal Infirmary, Glasgow.—This infirmary, which is the largest in Glasgow, is situated in Cathedral-square, Castle-street, and has car communication with every part of the city. St. Mungo's College is in the infirmary grounds.[1] The infirmary has, including the Ophthalmic Department, over 620 beds, the average number occupied in 1905 being 600. When the reconstruction of the infirmary, which was begun a year ago, is completed it will have about 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. Wards are set apart for the teaching of Women Students. At the Out-door Department the attendances in 1905 numbered over 62 000. In addition to the large medical and surgical departments there are departments for special diseases—viz, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and nine house surgeons, having a legal qualification in medicine and surgery, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. A fully equipped Electrical Pavilion was opened a few years ago and year by year the latest and most approved apparatus for diagnosis and treatment has been added. The fees for hospital attendance, including clinical lectures and tutorial instruction, attendance at the out-door department, at the pathological department, post-mortem examinations, and the use of the museum, which has recently been re-arranged and catalogued, are as follows: For one year, £10 10*s.*; for six months, £6 6*s.*; for three months £4 4*s.* Students who have paid fees to the amount of £21 to the Glasgow Royal Infirmary shall be permitted to attend in any subsequent year or years one winter and one summer course of instruction in the infirmary without further payment; and students who have paid to any other hospital in the United Kingdom fees, being not less than £21, in virtue of which they are entitled to attend without further payment, shall be admitted as students of the Royal Infirmary on payment of £3 3*s.* for six months or £1 11*s.* 6*d.* for three months.

Staff.—Consulting Surgeon for Diseases of the Eye: Dr.

---

[1] See section "Medical Schools with Full Curriculum."

A. Maitland Ramsay. Visiting Physicians: Dr. D. S. Middleton, Dr. J. Lindsay Steven, Dr. T. K. Monro, Dr. W. K. Hunter, and Dr. J. M. Cowan. Visiting Surgeons: Mr. John Barlow, Mr. J. A. Adams, Mr. David Newman, Mr. Q. McLennan, Mr. J. H. Pringle, Mr. H. Rutherfurd, and Mr. P. Paterson. Surgeon for Diseases of the Throat and Nose and Consulting Medical Electrician: Mr. J. Macintyre. Gynæcologist: Dr. J. K. Kelly. Surgeon for Diseases of the Ear: Mr. J. Kerr Love. Pathologist and Curator of Museum: Dr. Charles Workman. Assistant Pathologist: Dr. Mary Baird Hannay. Bacteriologist: Mr. David McCrorie. Assistant Bacteriologist: Mr. J. A. Campbell. Medical Electrician: Mr. J. R. Riddell. Assistant Medical Electricians: Dr. Samuel Capie, Dr. A. Jubb, and Katharine M. Chapman, L.R.C.P. Edin. Anæsthetist: Dr. A. Laurie Watson. Vaccinator: Dr. H. H. Borland. Dispensary Physicians: Dr. J. B. McK. Anderson, Mr. David McCrorie, Dr. Hugh McLaren, Dr. Norman Macnair, and Dr. John Henderson. Extra Dispensary Physicians: Dr. Campbell S. Marshall, Dr. James Scott, and Dr. J. T. McLachlan. Dispensary Surgeons: Mr. A. N. McGregor, Mr. John Patrick, Mr. John A. C. Macewen, Mr. A. C. Faulds, Mr. Thomas Kay, and Mr. Robert Ramsey. Extra Dispensary Surgeons: Mr. James Battersby, Mr. Donald Duff, and Mr. W. H. Steel. *Dispensary Specialists*:—Diseases of Women: Dr. J. K. Kelly; Diseases of the Ear: Mr. J. Kerr Love and Dr. James Adam; Diseases of the Skin: Dr. Alexander Morton; Diseases of the Throat and Nose: Dr. R. Fullerton; Diseases of the Eye: Dr. J. Rowan and Dr. H. W. Thomson; Diseases of the Teeth: Dr. W. Taylor. Superintendent: Dr. J. Maxtone Thom.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH, 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for out-door Ear, Nose, and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeon: Dr. Joseph Bell. Surgeons: Dr. William George Sym, Dr. Logan Turner, Dr. Malcolm Farquharson, Dr. John Cumming, Dr. J. V. Paterson, and Dr. E. M. Lithgow. Dental Surgeon: Mr. G. W. Watson. Treasurer and Secretary: Mr. J. P. Watson, W.S., 13, Hill-street.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 420. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eleven resident assistants are appointed annually, without salary, from those who have completed their course. *The fee for hospital attendance is* £10 10*s*., and the fees for clinical instruction are £3 3*s*. for Winter Session and £2 2*s*. for Summer Session.

Staff—Honorary Consulting Physicians: Dr. G. P. Tennant and Sir W. T. Gairdner, K.C.B. Visiting Physicians: Professor Sir T. McCall Anderson, Dr. J. Finlayson, Dr. S. Gemmell, and Dr. R. Stockman. Physicians for Diseases of Women: Dr. W. L. Reid and Professor M. Cameron. Assistant Physicians: Dr. J. Alexander, Dr. W. G. Dun, Dr. R. B. Ness, and Dr. Wm. MacLennan. Dispensary Physicians: Dr. Jas. Carslaw, Dr. John M. Cowan, Dr. John S. M'Kendrick, Dr. Robt. Fullarton, Dr. J. C. McClure, and Dr. F. Charteris. Dispensary Physicians for Diseases of Women: Dr. J. M. M. Kerr and Dr. E. H. L. Oliphant. Honorary Consulting Ophthalmic Surgeon: Dr. T. Reid. Honorary Consulting Surgeon: Dr. Alex. Patterson. Visiting Surgeons: Professor Sir Hector C. Cameron, Professor Sir W. Macewen, Dr. J. C. Renton, Dr. G. T. Beatson, C.B., Dr. T. K. Dalziel, and Dr. J. H. Nicoll. Assistant Surgeons: Dr. D. Macartney, Dr. R. Kennedy, Dr. A. A. Young, Dr. G. B. Buchanan, Dr. J. Morton, and Dr. G. H. Edington. Dispensary Surgeons: Dr. F. Macrae, Dr. Alex. MacLennan, Dr. Archd. Young, and Dr. M. L. Taylor. Extra Dispensary Physicians: Dr. A. B. Sloan, Dr. John Gracie, Dr. L. Findlay, and Dr. Duncan. Dispensary Aural Surgeon: Dr. T. Barr. Extra Dispensary Surgeons: Dr. W. W. Christie, Dr. C. C. Cuthbert, and Dr. A. H. Edwards. Dispensary Throat Surgeon: Dr. J. W. Downie. Vaccinator: Dr. J. W. Nicol. Pathologist: Professor R. Muir. Assistant Pathologists: Dr. M. L. Taylor and Dr. John H. Teacher. Dental Surgeon: Mr. W. D. Woodburn, L.D.S. Medical Superintendent: Dr. D. J. Mackintosh, M.V.O.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow.—The Hospital at Garnethill was opened in December, 1882, and in June, 1903, a country branch consisting of two wards was opened at Drumchapel. The number of beds in the town hospital and country branch together is 100. A specially designed Dispensary, or Out-patient Department, was opened in October, 1888, in West Graham-street. The whole institution is for non-infectious cases and is available to medical students for clinical instruction in the diseases peculiar to childhood. Classes are formed both at Hospital and Dispensary at the beginning of the University session in October. Students may be enrolled at any time. *Fee* £1 1*s*. per annum, admitting to both Hospital and Dispensary. Particulars on applying to the House Surgeon, 45, Scott-street, Garnethill, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (29 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 971; out- or dispensary patients, 9989. Operations on Wednesdays and Saturdays. Honorary Consulting Surgeon: Dr. D. N. Knox. Surgeon: Dr. A. Maitland Ramsay. Assistant Surgeon: Dr. John Rowan. Junior Assistant Surgeons: Dr. H. Wright Thomson and Dr. John Gilchrist. Pathologist: Dr. Hugh Walker. Bacteriologist: Dr. J. Campbell McClure. Electrician: Dr. John Gilchrist. House Surgeon: Dr. G. C. Neilson. This institution is the Ophthalmic Department of the Royal Infirmary. A post-graduate course is given by Dr. Ramsay and assistants during November and December. Clinical instruction is given in the summer session to students of the University of Queen Margaret College and in winter to students of St. Mungo's College and to all who take the class.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The Infirmary now consists of two large buildings—that in Berkeley-street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary. The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves. The average number of new patients for the last ten years has been 20,192·3, and the total number of cases treated in 1905 was 28,995. The Medical Staff is as follows:—Surgeons: Dr. Thomas S. Meighan, Dr. A. Freeland Fergus, Dr. Andrew Wilson, Dr. James Hinshelwood, Dr. Leslie Buchanan, and Dr. W. Ernest F. Thomson. Assistant Surgeons: Dr. A. Lewis M'Millan, Dr. Henry L. G. Leask, Dr. W. Cochrane Murray, Dr. Brownlow Riddell, Dr. Arthur J. Ballantyne, and Dr. A. A. Macfarlane. Pathologist: Dr. W. B. Inglis Pollock. House Surgeon: Dr. A. M. Pollock. Assistant House Surgeon: Dr. J. B. Morton.

Regulations as to Attendance of Students.—(1) Gentlemen may attend as students on payment to the treasurer of the following fees:—For six months £1 1*s*., 12 months £2 2*s*. (2) All students when duly entered in the Infirmary Register [illegible] or every member may attend the clinical instruc of the medical staff on production of their tickets. The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary. Students have the privilege of being present in the Dispensaries at such hours as are arranged. They may enter the wards along with the surgeon whose clinique they are attending when he visits his patients. They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation. Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. Joint Secretaries and acting Treasurers: William George Black and Harold John Black, 83, West Regent-street. The medical session opens in October.

IRISH SCHOOLS OF MEDICINE.[1]

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. A refreshment-room is now open where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences Oct. 1st; Summer Session, April 1st. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green, W., Dublin.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Ten Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £20 each. Two are tenable by matriculated students of the first, second, third, fourth, and fifth years of their course respectively. The examinations for Scholarships take place at the commencement of the session. Class Prizes are awarded at examinations which take place at the close of the session. The Exhibitions, &c., of the Royal University of Ireland are also open to students. Lectures in Medicine at Queen's College, Belfast, will commence on Oct. 16th and end on March 31st. The Summer Medical Classes will begin on May 1st, except Botany, which begins on April 2nd. The new Chemical Buildings contain, in addition to a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark-room for photographic purposes, balance room, &c., provided with all modern appliances. Special facilities are given to those who wish to pursue original research. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The medical museum is in the same building. The physiological department comprises (1) a large and well-lighted class-room for practical physiology and histology, fitted with motor and shafting, and with arrangements for lantern projection; (2) a laboratory for chemical physiology; (3) an apparatus-room; (4) a dark-room; (5) private research-rooms; and (6) a centrifuge-room. The Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The pharmaceutical laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines. Clinical instruction is given at the Royal Victoria Hospital, the medical staff of which is as follows:—Physicians: Sir William Whitla, Professor James A. Lindsay, Dr. William Calwell, and Dr. H. L. McKisack. Surgeons: Mr. J. Walton Browne, Professor T. Sinclair, Mr. A. B. Mitchell, and Mr. T. S. Kirk. Gynæcologist: Professor J. W. Byers. Surgeon for Diseases of the Eye, Ear, and Throat: Mr. Joseph Nelson. Pathologist: Professor W. St.C. Symmers. Physician for Diseases of the Skin: Dr. W. Calwell. Assistant Physicians: Dr. W. B. McQuitty and Dr. J. S. Morrow. Assistant Surgeons: Mr. Robert Campbell and Mr. Andrew Fullerton. Assistant to the Gynæcologist: Mr. R. J. Johnstone. Assistant Surgeon Eye, Ear, and Throat Department: Mr. James A. Craig. Assistant to the Pathologist: Dr. S. H. G. Blakely. Administrators of Anæsthetics: Dr. V. G. L. Fielden, Dr. Howard Stevenson, and Dr. M. B. Smyth. Medical Electrician: Dr. J. C. Rankin. Hæmatologist: Dr. Thomas Houston. Refraction Assistant: Dr. Henry Hanna. Registrars: Dr. J. E. MacIlwaine and Dr. S. T. Irwin. The Ulster Hospital for Diseases of Women and Children, the Maternity Hospital, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, the Hospital for Sick Children, and the District Lunatic Asylum are open to students. A pamphlet containing full information regarding the medical classes in Queen's College and the facilities for clinical instruction in the various hospitals can be had free on application to the Registrar, Queen's College, Belfast, or to the Secretary, Medical Staff, Royal Victoria Hospital, Belfast.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting room, supplied with electric light, with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course.

Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are open to students in their first four years and the Blayney Scholarship, value £32, and a Senior Exhibition to students in their fifth year.

Students can attend the North and South Infirmaries, the Cork Union Hospital, the Cork Fever Hospital, the County and City of Cork Lying-in Hospital, the Cork Maternity, the County and City of Cork Hospital for Diseases of Women and Children, the Cork Eye, Ear, and Throat Hospital, and the Cork District Lunatic Asylum.

Staff, North Infirmary.—Physicians: Dr. D. D. Donovan and Dr. E. Magner. Surgeons: Dr. Cotter, Dr. C. Y. Pearson, Dr. N. J. Hobart, and Dr. D. J. O'Mahony. Assistant Physician: Dr. R. B. Dalton. Assistant Surgeons: Dr. J. Dundon and Dr. R. P. Byrne. Pathologist: Dr. Denis Murphy. House Physician: Dr. D. F. Hegarty. House Surgeon: Dr. D. M. Donovan. Surgeon Dentist: Mr. H. O'Keeffe.

Staff, South Charitable Infirmary.—Physicians: Dr. P. T. O'Sullivan and Dr. N. I. Townsend. Surgeons: Dr. H. R. Townsend, Dr. H. Corby, and Dr. T. G. Atkins. Ophthalmic Surgeon: Dr. A. W. Sandford. Extern Physicians: Dr. D. J. O'Flynn and Dr. E. W. Allsom. Extern Surgeon: Dr. R. P. Crosbie. House Surgeon: Dr. J. P. Higgins. Dentist: Mr. T. C. Butterfield.

THE MEDICAL SCHOOL OF THE CATHOLIC UNIVERSITY, IRELAND, DUBLIN.—Founded in 1855, it is now the largest medical school in Ireland. It prepares students specially for the examinations of the Royal University and the Conjoint Colleges of Ireland and Edinburgh, but its lectures and practical courses are recognised by all the Licensing Bodies in Great Britain and Ireland. In addition to the ordinary medical examinations it prepares students for the D.P.H. and for the various higher University *examinations in* Pathology, Physiology, Chemistry, &c. Six exhibitions and numerous *gold and silver medals are offered* annually for competition. The school opens for dissections on Oct. 1st; the winter lectures begin on Nov. 2nd. The Summer Session commences on April 1st.

---

[1] For Scholarships see p. 633 et seq.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Galway.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which may be appointed Demonstrator, is offered annually for competition tenable for one year by a student who shall *have attended the Medical School of the College for at least* two sessions and shall have obtained a Degree in Arts or Medicine or a *Diploma* in Medicine from a *Licensing Body.* Scholarship examinations are held at the commencement *and those for Sessional Prizes at the close of each* session. The Medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom. The College contains well lighted and ventilated dissecting room and anatomical lecture theatre; physiological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as a large natural history and geological museum and an extensive library in which students can read and from which they can borrow books. Clinical instruction is given *in the Galway Hospital and in the Galway Union* and *Fever Hospitals.* The following constitute the medical staff of the Galway Hospital.—Physicians: Professor Kinkead and Professor Lynham. Surgeons: Professor Pye, Professor Colahan, and Professor Brereton. Gynæcologist: Professor Kinkead. House Surgeon: Mr. O'Brien. Instruction at the Galway Union and Fever Hospital is given by Professor Colahan and Mr. McDonogh. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a part is at the disposal of the College Athletic Union. A prospectus *containing* full *information* as to courses of lectures, scholarships, and fees for classes can be obtained *on application to the Registrar, Queen's* College, Galway.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine *months'* hospital attendance, £12 12s.; six months, £8 8s. Summer, three months, £5 5s.

Staff.—Physicians: Dr. James Little, Dr. Wallace Beatty, and Dr. H. T. Bewley. Surgeons: Mr. F. T. Heuston and Mr. T. E. *Gordon. Obstetric Surgeon:* Sir W. J. Smyly. Ophthalmic Surgeon: Dr. H. R. Swanzy. Throat Surgeon: Dr. S. Horace Law. Pathologists and Bacteriologists: Dr. J. Alfred Scott and Dr. W. Geoffrey Harvey. Dental Surgeons: Dr. Theodore Stack and Mr. John Stanton. *Assistant Physician:* Dr. G. Peacocke. Assistant Surgeon: Dr. K. E. Levison-Gower Gunn. House Surgeons: Dr. King Edwards and *Dr. George Wright.*

Two resident surgeons are elected yearly and three resident pupils half-yearly. At the termination *of the session* prizes in Clinical Medicine and Surgery and in Obstetric Medicine will be awarded.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a *silver medal,* will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology, Gynæcology, and *Dermatology.*

The certificates of attendance are recognised by all the Universities and *licensing* bodies in the United Kingdom. Further particulars may be obtained from Mr. F. T. Heuston.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, *Dublin.—This* hospital contains nearly 70 beds and consists of two divisions, one of which is devoted to lying-in cases and *the other* to the treatment of diseases peculiar to women. The *practice of this hospital is* one of the largest in Ireland; nearly 18,000 cases are treated annually, either as *intern or extern patients. Lectures* are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary *held by the Master and his* assistants, at which practical instruction in gynæcology is given. This is the largest dispensary of its kind in Dublin. There is no extra charge for attendance at this dispensary. There is accommodation for intern pupils who enjoy exceptional advantages *of acquiring a thorough knowledge of this branch of their* profession. Lady medical students can reside in the hospital. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local *Government Board* as a full legal midwifery qualification. The resident quarters *have been* much enlarged. *A* billiard table has been erected for the use of students. Fees: Extern pupils for full course of six months, £8 8s.; three months, £4 4s. Intern pupils, one month, £4 4s.; each consecutive month, £3 3s.; six months, £18 18s.; board and lodging in the hospital, 18s. per week. Lady students' intern, one *month,* £5 5s.; each consecutive month, £4 4s. Registration fee, in advance, 10s. 6*d.* Students can enter for *attendance at* any time, but preference is given to those entering from the first day *of* the month. Further particulars may be had *on* application to the Master or the Registrar at the hospital.

Staff.—Consulting Physicians: Sir John Banks, Sir John W. Moore, *and Dr. J. M. Redmond. Consulting Surgeons:* Dr. F. T. Heuston and Dr. F. W. Kidd. Pathologist: Dr. E. J. McWeeney. Pathological *Analyst:* Sir *C. A.* Cameron. Master: Dr. T. G. Stevens. Assistant Masters: Dr. M. J. Gibson and Dr. Ronald S. Orbell. Registrar: *Fred. A. Heney.*

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.—Special classes *for students* commencing their hospital studies will be held in the wards during the months of October, November, and December. They will embrace the elements of Medicine and Surgery, including note taking. The surgical operating theatre, which has recently been erected, is equipped *upon the most approved* principles and is thoroughly in accord with modern surgical requirements. Instruction in the *Diseases of Women* is given Tuesday and Friday at 10 A M. by Sir Arthur V. Macan. There is a special wing *devoted to fever cases* and regular clinical *instruction* is given by the members of the medical staff throughout the Winter and Summer Sessions. *Pathological* and Bacteriological Demonstrations will be given each Friday at 10 30 A.M. during the Winter and Summer *Sessions* in the new Pathological Laboratory. A new *department* has been opened for the special treatment of Throat, Nose, and Ear diseases. Instruction will be given in these subjects and in the use of the Laryngoscope and Otoscope to senior *students* on Tuesdays and Fridays. Opportunities are given the members of the hospital class *of* seeing the various applications of the x rays to the diagnosis and *treatment* of injury and disease Opportunities are *here* also afforded *for the* diagnosis and treatment of the numerous minor ailments not met with in the hospital wards. Demonstrations are *given* upon Diseases of the Skin. A resident surgeon, with salary, is appointed annually. The election takes place at the end of December. Four Resident *Pupils* are appointed each half-year. Six Surgical Dressers and six Clinical Clerks are appointed each *month.*

Prizes and Medals.—Clinical medals and prizes will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M D., S.F.T C D. Candidates who fail *to obtain* these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit. The next *examination* will be held on Monday, April 22nd, 1907.

Fees.—Winter and summer session, £12 12s.; winter session (six months), £8 8s.; and summer session (three months), £5 5s. The practice of this hospital is *open to* students of Medicine in attendance on schools *other than* the School *of Physic,* the certificates being recognised by the Royal University and Royal Colleges *of Surgeons of* England, Ireland, and Scotland.

MERCER'S HOSPITAL.—This hospital, *founded in 1707,* is situated in the *centre* of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal *College of Surgeons.*

the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large out-patient department and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. Five Resident Pupils, each for six months, and Clinical Clerks and Dressers are appointed monthly from amongst the most deserving members of the class.

The Winter Session will commence on Oct. 1st.

Fees.—Winter, six months, £8 8*s.*; Summer, three months, £5 5*s.*; nine months, £12 12*s.*

For further particulars apply to Dr. R. Charles B. Maunsell, 32, Lower Baggot-street, Dublin.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—Physicians: Sir John William Moore, Dr. James Craig, and Dr. Edward E. Lennon. Surgeons: Sir L. H. Ormsby, Mr. W. J. Hepburn, Mr. William Taylor, Mr. R. Lane Joynt, and Mr. F. Conway Dwyer. Gynæcologist: Dr. F. W. Kidd. Clinical Assistants: Dr. William Boxwell and Dr. Henry Stokes. Pathologist: Professor Arthur H. White. This hospital was founded in 1753 and now contains 160 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the Hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Six Medical Clinical Clerks and Twelve Surgical Resident Pupils and Dressers are appointed every six months, and a House Surgeon and two Clinical Assistants are elected annually. The session will open on Oct. 1st. A prospectus giving the complete arrangements for the Medical and Surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. William Taylor, 47, Fitzwilliam-square, Dublin.

MATER MISERICORDIÆ HOSPITAL, Dublin.—Consulting Physician: Sir Francis R. Cruise. Consulting Surgeon: Mr. Charles Coppinger. Physicians: Sir Christopher Nixon, Bart., Dr. Joseph Redmond, Dr. John Murphy, and Dr. Martin Dempsey. Surgeons: Sir Arthur Chance, Mr. John Lentaigne, and Mr. Alexander Blaney. Assistant Physician: Dr. John O'Donnell. Assistant Surgeon: Mr. Curran. Temporary Assistant Surgeon: Mr. D. Farnan. Obstetric Physician: Dr. Robert Farnan. Ophthalmic Surgeon: Mr. Louis Werner. Dental Surgeon: Mr. E. Sheridan. Pathologist: Dr. Edmond McWeeney. Anæsthetist and Surgical Registrar: Dr. Patrick O Farrell. This hospital, the largest in Dublin, at present containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Fridays, and Saturdays at 11 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Two House Physicians, six House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. Private Wards have been opened for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses have been opened in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes &c., may be obtained from the Secretary, Medical Board.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic Diseases. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 12 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students, but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. For prospectuses apply to Sir W. Thomson, C.B., Hon. Treasurer, 54, Stephen's-green East; or to Dr. J. O'Carroll, Honorary Secretary, 43, Merrion-square, Dublin.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest gynæcological as well as maternity hospital in the British empire. Qualified men who take out a course of two or three months' duration during the autumn, winter, or spring periods obtain (if they show keenness and capacity) one or more forceps applications and a certain number of minor gynæcological operations. Unqualified students can also enter at any time for the practice of the hospital and have access, not alone to the maternity and gynæcological wards, but also to the pathological laboratory attached to the hospital. The residential quarters have undergone considerable improvement and afford comfortable accommodation. Valuable appointments are periodically filled by qualified students who have obtained the hospital diploma. For further particulars apply to Mr. E. Hastings Tweedy, Master.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 30th, 1828.

FOREIGN DEPARTMENT.

NICOLAS CHERVIN'S RESEARCHES ON THE NATURE OF YELLOW FEVER.

THIS distinguished individual has been engaged, during nearly the whole of his life, in the study of this formidable disease; neither dangers nor pecuniary sacrifices could change his intention to visit almost every part of America where this calamity reigns. He did not return, until after ten years of incessant study and incredible toil, to his native country, to reap the fruits of his admirable zeal. ......[1] Chervin has made more than FIVE HUNDRED post-mortem examinations. He has often *swallowed* some of the *black fluid* found in the stomach of the deceased; he *rubbed the whole surface of his body with it, and always remained free from infection.*

The following are the general results of his inquiries:—Of more than 500 competent practitioners, only 48 are in favour of the contagiousness of the yellow fever, 483 being decidedly against it. In those parts of America where it most frequently rages, nobody believes in contagion; the extension of the disease seems entirely owing to the atmospheric constitution, and to local causes; the latter consist, partly, in putrid effluvia; there exists, in no case, a clear proof of contagion having taken place, and all assertions to the contrary are founded either on false testimonies, on defective observations, or on erroneous inferences from correct observations.

[1] A "concise account of his travels" fills this lacuna.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY.

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
LONDON UNIVERSITY	No. 1.	£40 per annum.	1 year.	Awarded to the most meritorious of those candidates, whether internal or external, who, having passed the whole Intermediate Examination in Medicine at one time, have been awarded marks of distinction in (1) ANATOMY, or (2) PHYSIOLOGY, or (3) PHARMACOLOGY.	No candidate will be allowed to receive the income of more than one scholarship at the same time.
	No. 2.	£40 per annum.	1 year.		
	No. 3.	£30 per annum.	1 year.		
SOCIETY OF APOTHECARIES OF LONDON	Gillson.	£90 per annum.	1 year.	Open to Licentiates of the Society, or to candidates for the Society's Diploma who obtain such Diploma within six months of their election to the scholarship.	Candidates must be under 35 years of age.
ST. BARTHOLOMEW'S MEDICAL SCHOOL	Entrance Scholarships. No. 1.	£75.	—	Open Competitive Examination in not more than three nor fewer than two of CHEMISTRY, PHYSICS, ZOOLOGY, BOTANY, PHYSIOLOGY, ANATOMY.	Full or University Course at St. Bartholomew's Hospital.
	" No. 2.	£75.	—		Ditto
	" No. 3	£150.	—	Open Competitive Examination in not fewer than three of the following:— CHEMISTRY, PHYSICS, BOTANY, ZOOLOGY, PHYSIOLOGY.	Full Course at St. Bartholomew's Hospital.
	Preliminary Scientific Exhibition.	£50.	—		Ditto.
	Jeaffreson Exhibition.	£20.	—	Open Competitive Examination in LATIN, MATHEMATICS, and GREEK, or FRENCH, or GERMAN.	Ditto.
	Shuter Scholarship.	£50.	—	Competitive Examination among Cambridge Graduates in ANATOMY and PHYSIOLOGY.	Ditto.
	Junior Scholarships. " No. 1.	£30.	—	Competitive Examination among Students in ANATOMY and BIOLOGY.	Study at St. Bartholomew's Hospital.
	" No. 2.	£20.	—	Ditto.	Ditto.
	" No. 3.	£25.	—	Competitive Examination in CHEMISTRY, PHYSICS, and HISTOLOGY.	Ditto.
	" No. 4.	£15.	—	Ditto	Ditto.
	Senior Scholarship.	£50.	—	Competitive Examination among Students in ANATOMY, PHYSIOLOGY, and CHEMISTRY.	Ditto.
	Kirkes Scholarship.	£30 and Medal.	—	Competitive Examination among Students in CLINICAL MEDICINE.	Ditto.
	Brackenbury Scholarships. " No. 1.	£39.	—	Competitive Examination among Students in MEDICINE.	Ditto.
	" No. 2.	£39.	—	Competitive Examination among Students in SURGERY.	Ditto.
	Lawrence Scholarship.	£45 and Medal.	—	Competitive Examination among Students in SURGERY, MEDICINE, and MIDWIFERY.	Ditto.
	Sir Geo. Burrows Prize.	£10.	—	Competitive Examination in PATHOLOGY among Students.	Ditto.
	Skynner Prize.	13 guineas.	—	Competitive Examination in REGIONAL and MORBID ANATOMY among Students.	Ditto.
	Matthews Duncan Medal and Prize.	£20.	—	Competitive Examination among Students in MIDWIFERY and GYNÆCOLOGY.	Ditto.
	Luther Holden Research Scholarship in Surgery. (And other Prizes and Medals *of less value*).	£105.	—	By Election.	Ditto.
CHARING CROSS HOSPITAL AND COLLEGE	Entrance Scholarships, open to students at the commencement of curriculum. Livingstone.	100 guineas.	—	The Livingstone and Huxley Scholarships are awarded *annually* at the commencement of each Winter Session, after a competitive examination in the *following* groups *of* subjects:— (1) ENGLISH, including LANGUAGE, HISTORY, and GEOGRAPHY; (2) LATIN and *any one of the following* three languages—GREEK, FRENCH, and GERMAN, (3) MATHEMATICS, including ARITHMETIC, ALGEBRA, and GEOMETRY, and MECHANICS, including STATICS and DYNAMICS; (4) INORGANIC CHEMISTRY and EXPERIMENTAL PHYSICS, including ACOUSTICS, HEAT, MAGNETISM, ELECTRICITY, and OPTICS; and (5) ANIMAL and VEGETABLE BIOLOGY. No Candidate may offer himself for examination in more than three of the above groups of subjects, the selection of the groups being left entirely to the Candidate.	Open to all general students.
	...	60 "	—		Open to all general students.
	Huxley.	55 "	—		For sons of medical men.
	...	40 "	—		Open to all general students.
	...	30 "	—		For dental students.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
CHARING - CROSS HOSPITAL AND COLLEGE—*continued.*	Epsom Scholarship.	Free education.	—	....	Epsom Foundation Scholars who have passed Preliminary Scientific M.B. *Lond.* Univ.
	Universities Scholarship (1) Universities Scholarship (2)	72 guineas. 72 "	—	Examination in Anatomy and Physiology, including Histology.	Oxford Students who have passed first M.B. Exam. Cambridge students who have passed second M.B. Exam. London students who have passed Intermediate Exam. in Med. who have not entered at any London Medical School.
	Llewellyn Scholarship.	£25	....	Awarded annually to the Student of not more than five years' standing who, in the opinion of the School Committee, shall have distinguished himself the most at the Prize Examinations in the following subjects, viz.:—Medicine, Surgery, Midwifery, Pathology, Therapeutics, Forensic Medicine, Public Health, Psychological Medicine, Ophthalmology, Practical Medicine, Practical Midwifery.	None.
	Huxley Medal with Prize.	£10.	—	Competitive Examination in Anatomy and Physiology at end of Second Winter Session.	—
	Golding Prize.	£10.	—	Competitive Examination among First-year Students in Anatomy and Physiology.	Students must have attended the Classes in each subject at this School.
	The Dr. T. H. Green Prize for Clinical Medicine.	5 guineas.	......	Given annually to the Student who does the best work upon some special subject involving simple clinical observation in the wards or clinical laboratory and on the result of a practical examination on cases in the wards.	....
ST. GEORGE'S HOSPITAL	Entrance Scholarships. No. 1.	70 guineas	—	Competitive Examination in Anatomy and Physiology.	......
	" No. 2.	£50.	—	Ditto.	......
	Wm. Brown Exhibition.	£100 per annum.	2 years.	Competitive Examination among Perpetual Pupils having registrable qualification in the Practice of Medicine, Midwifery, and Surgery.	Study at St. George's School.
	"	£40 " "	3 years.	Competitive Essay and Submission of Original Work by Perpetual Pupils qualified not more than three years previously.	Ditto.
	Allingham Scholarship in Surgery.	Interest on £1500.	—	Competitive Essay for Students qualified not more than three years.	....
	Brackenbury Prize in Medicine.	Interest on £1103.	—	Competitive Examination among Students of not more than five years' standing.	None.
	Brackenbury Prize in Surgery.	Interest on £1103.	—	Competitive Examination among Students of not more than five years' standing.	None.
	Treasurer's Prize.	£10 10s.	—	Proficiency in Clinical Examination of three Medical and three Surgical Cases, together with a written Examination in Medicine, Surgery, and Midwifery.	None.
	H. C. Johnson Memorial Prize.	£10 10s.	—	Competitive Examination in Practical Anatomy.	None.
	Pollock Prize.	Interest on £372.	—	Competitive Examination in Physiology, Physiological Chemistry, and Histology.	None.
	Clarke Prize. Thompson Medal. Brodie Prize.	Interest on £309. Interest on £165. Interest on £220.	— — —	Awarded for Clinical Reports and Commentaries.	None.
	Webb Prize.	Interest on £1000.	—	Competitive Examination among Perpetual Pupils in Bacteriology.	None.
GUY'S HOSPITAL ...	Entrance Scholarships. No. 1.	£100.	—	Open Competitive Examination among Candidates under twenty years of age in Latin, English, Greek or French or German, Arithmetic, Euclid, and Algebra.	Course at Guy's Hospital.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

EDINBURGH UNIVERSITY —*continued.*	* Crichton Research Scholarships in Anatomy, Physiology, Materia Medica, and Pathology.	£100 each per annum.	1, 2, or 3 years.	Competitive Examination for Graduates of the University.	Continued research.
	* Mouat Scholarship.	£55 and Medal.	1 year.	Class and Degree Examinations in PRACTICE OF PHYSIC (MEDICINE).	Continued study in Medicine.
	* Grierson Bursary. " No. 4.	£10.	1 year.	Competitive Examination in MATERIA MEDICA.	Continued study.
	" No. 5.	£10.	1 year.	Competitive Examination in PATHOLOGY.	Ditto.
	* M'Cosh Graduate's Bursary and M'Cosh Medical Bursary (for Research).	Income of £5500.	1 year.	Distinction in Professional Subjects, and sufficient knowledge of FOREIGN LANGUAGES.	Study or Research in Medical Schools of Europe.
	* Gunning Victoria Jubilee Prizes (2 awarded annually).	Each £50.	--	Thesis or Original Research in ANATOMY, PHYSIOLOGY, ZOOLOGY, BOTANY, CHEMISTRY, MATERIA MEDICA, SURGERY, PRACTICE OF PHYSIC, PATHOLOGY, OBSTETRICS, and MEDICAL JURISPRUDENCE and PUBLIC HEALTH, respectively.	
	* Theses Gold Medals.	--	--	Candidates for M.D. who present Theses of high merit.	
	Conan Doyle Prize.	£32.	--	Most distinguished Graduate of year from South Africa.	
	* Wightman Prize.	£12.	--	Competitive Reports on Clinical Medicine Cases.	
	* Beaney Prize.	£32 10s	--	Highest Marks in ANATOMY, SURGERY, and CLINICAL SURGERY, in M.B. and Ch.B. Examinations.	
	* Ellis Prize.	£28 per annum.	--	Essay on ANIMAL OR VEGETABLE PHYSIOLOGY.	
	* Cameron Prize.	Annual Proceeds of £2000.	--	Most valuable addition to PRACTICAL THERAPEUTICS during preceding 5 years.	
	* Milner Fothergill Gold Medal.	About £20.	--	Essay on PHARMACOLOGICAL or THERAPEUTIC SUBJECT.	
	† Mackay Smith Scholarship in Chemistry.	£25 per annum.	2 years.	Competitive Examination in CHEMISTRY among University Students.	Continued study of Chemistry.
	† Houldsworth Scholarship.	£40.	1 year.	Competitive Examination in MATERIA MEDICA among University Students or Graduates.	Research in Pharmacology.
	† Mackenzie Bursaries (2 annually).	£20.	......	Industry and Skill in PRACTICAL ANATOMY.	
	* Pattison Prize.	About £11 7s. 6d.	......	Competitive Reports on CLINICAL SURGERY CASES.	
	Dobbie Smith Gold Medal.	--	--	Essay on BOTANICAL SUBJECT.	
	Anderson Henry Prize.	Proceeds of £300 accum. for 3 years.	--	Ditto.	
	Gilfillan Memorial Prize.	About £10.	--	Most distinguished Woman Graduate of year.	
LASGOW UNIVERSITY..	Two Highland Society Bursaries.	£25 each.	5 years.	Open 1906. Awarded on results of Preliminary Examination.	Open to medical students of Highland descent.
	Mackintosh Mental Science Bursary.	£31.	1 year.	--	Open for competition to students of medicine of either sex attending the lectures on Insanity.
	Monteith Bursary.	£21.	2 years.	Vacant 1906. Examination in ANATOMY and PHYSIOLOGY.	Awarded on results of Second Professional Examination.
	Dr. Thos. Gibson Bursary.	£36.	4 years.	Vacant 1906. Competition by Students at the First Professional Examination.	Open to medical students preparing to be missionaries in connexion with the Church of Scotland.
	Coats Scholarship.	£80.	1 year.	Special Examination in PATHOLOGY. Vacant 1907.	Open to Graduates in Medicine of not more than three years' standing. Holder to prosecute research in Pathology.
	John Macfarlane Bursary.	£40.	3 years.	Vacant 1908. Examination in ANATOMY, CHEMISTRY, and BOTANY.	Open to medical students entering on their Second Winter Session.
	Lorimer Bursary.	£24.	3 years.	Vacant 1906. Examination in ANATOMY, CHEMISTRY, and BOTANY.	Open to medical students entering on their Second Winter Session.

* For Students entering on or in their Fourth or Fifth Year, or for Graduates.
† For Students of any year (or standing of candidates not stated).

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
GLASGOW UNIVERSITY—*continued.*	One Armagh Bursary in Medicine.	£48.	3 years.	Competition by Students who are presenting themselves for the Final Examination for the degree of M.A. with Honours in MENTAL PHILOSOPHY.	Open to students of either sex who have taken the course of study for graduation in Arts and intend to study Medicine.
	One Armagh Bursary in Medicine.	£48.	2 years.	Competition by Students who are presenting themselves for the Final Examination for the degree of M.A. with Honours in CLASSICS.	Ditto.
	Taylor Bursary.	£7.	4 years.	Appointment by the Senate. Vacant in 1906.	Open to students of either sex in any faculty.
	William Gardiner Bursary.	£14.	2 years.	Next vacancy 1907. Competition in PHYSIOLOGY, CHEMISTRY, and PHYSICS of PROFESSIONAL EXAMINATIONS.	Open to medical students of either sex.
	Rainy Bursary.	£20.	2 years.	Vacant 1906 Examination in ANATOMY, PHYSIOLOGY, CHEMISTRY, BOTANY, and ZOOLOGY.	Open to medical students entering on their Fourth Winter Session.
	Two Paterson Bursaries.	£25 and £20.	4 years.	Vacant 1906. Examination in MATHEMATICS and DYNAMICS.	Open to medical students of First or Second Session.
	Brunton Memorial Prize.	£10.	1 year.	Awarded annually to the most distinguished Graduate in MEDICINE of the year.	
	Dobbie Smith Gold Medal.	....	....	Awarded annually for the best essay on any subject within the limits of the science of BOTANY.	All matriculated students of 1905–6 or 1906–7 may be competitors.
	Two Arnott Prizes.	£25 and £15.	year.	Examination in PHYSIOLOGICAL PHYSICS &c.	
	Andrew and Bethia Stewart Bursary.	£50.	3 years.	Vacant 1906 Special Examination.	Candidates must be M.A. of Glasgow University.
	Weir Bursary.	£16.	1 year.	Awarded on result of Second and Third Professional Examinations.	
QUEEN'S COLLEGE, BELFAST	Ten Junior Scholarships for Matriculated Students, two for each of the five years' curriculum.	£20 each.	1 year.	Examination at the commencement of session.	Open to matriculated Medical Students of either sex.
ROYAL COLLEGE OF SURGEONS IN IRELAND, SCHOOLS OF SURGERY	Class Prizes.	£50.	....	Proficiency in Class Examination.	Open to student of class.
	Carmichael Scholarship.	£15.	....	Examination in ANATOMY, PHYSIOLOGY, HISTOLOGY, CHEMISTRY, MATERIA MEDICA, and PHARMACY.	Open to students of the third year.
	Mayne Scholarship.	£8.	....	SURGERY, MEDICINE, PATHOLOGY, MIDWIFERY, and DISEASES OF WOMEN.	Open to students of third and fourth year.
	Barker Bequest.	£31 10s.	....	For best DISSECTION.	Open to all medical students.
ROYAL UNIVERSITY OF IRELAND	Travelling Medical Scholarship.	£100.	....	The subjects are in rotation: (1) ANATOMY AND HISTOLOGY; and (2) PHYSIOLOGY AND PATHOLOGY.	Those who have passed the Medical Degrees Examination either in the year of the scholarship examination or in the year immediately preceding are alone eligible.
	Dr. Henry Hutchinson, Stewart Medical Scholarships.				
	" No. 1.	£10.	3 years.	Competition in the subjects of the second examination in MEDICINE.	Candidates must present themselves after the lapse of not more than one medical year from the time of passing the first examination in medicine.

THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES.

DURING the year some changes for the better have been made in the regulations for the Royal Army Medical Corps. The conditions of service in the medical department of the Royal Navy and in the Indian Medical Service remain much as they were at the date of the issue of the Students' Number in 1905; the few unimportant changes are, however, incorporated in this article. The marked improvement in the quality of the candidates for the services which was hoped for as the result of the beneficial alterations which have been introduced into the conditions of service cannot be said to have been realised yet. There is, however, a supply of candidates and it is true that the social standard of the selected candidates for the Royal Army Medical Corps has improved and that the process of weeding out before the London examination, however it may be effected, is doing good to the service, though even now some men who are considered undesirable manage to pass the portals. As to the medical qualifications of the competitors, there does not appear to be any great change since the Netley days though there may be a few more men who can write M.B. Lond. or F.R.C.S. Eng. after their names. An improvement in the professional knowledge and practical work of the lieutenants-on-probation passing through the Medical Staff College in London has, we believe, not been evident. The new regulations as regards pay for the civil side of the Indian Medical Service should go some way towards reinstating the service in the favour of the young medical man and his advisers, but as private practice up country is much less than in the old days we believe that a still more liberal scale of pay will have to be granted. We desire to call attention to a proposal which we make for the alteration of the date of first commission in the Indian Medical Service; the proposal will be found towards the end of the information which we print relative to that service. With reference to the course of instruction given at the Medical Staff College for the probationers of the Royal Army Medical Corps and the Indian Medical Service it cannot be said that at present the course is any improvement on that given in the old Army Medical School at Netley. The work of the lieutenants-on-probation is done at too high a pressure to be really valuable, but this defect, we believe, is recognised and can be easily remedied by extending the period of instruction. No doubt when the new college is built and all the work of the course is done there, close to the military hospital, much better arrangements will be made than at present exist. The new Army Medical College will, it is estimated, cost £250,000.

ROYAL NAVY MEDICAL SERVICE.

REGULATIONS FOR THE ENTRY OF CANDIDATES FOR COMMISSIONS IN THE MEDICAL DEPARTMENT OF THE ROYAL NAVY.

Every candidate for admission into the Medical Department of the Royal Navy must be not under 21 nor over 28 years of age on the day of the commencement of the competitive examination. He must produce an extract from the register of the date of his birth; or, in default, a declaration made before a magistrate, from one of his parents or other near relative, stating the date of birth. He must also produce a certificate of moral character, up to date, and a recommendation signed by a clergyman or magistrate, to whom he has been for some years personally known, or by the president or senior professor of the college at which he was educated.

He must be registered under the Medical Act in force, as qualified to practise medicine and surgery in Great Britain and Ireland.

He must declare (1) his age and date and place of birth; (2) that he is of pure European descent and the son either of natural-born British subjects or of parents naturalised in the United Kingdom; (3) that he labours under no mental or constitutional disease or weakness, nor any other imperfection or disability which may interfere with the most efficient discharge of the duties of a medical officer in any climate; (4) that he is ready to engage for general service at home or abroad, as required; (5) whether he holds, or has held, any commission or appointment in the public services; and (6) that he is registered under the Medical Act in force as duly qualified professionally, and what diplomas, &c., he holds.[1]

He must be free from organic or other diseases, and his physical fitness will be determined by a Board of Medical Officers, who are to certify that his vision comes up to the required standard, which will be ascertained by the use of Snellen's Test Types. The certificates of registration, character, and birth, must accompany the declaration, which is to be filled up and returned as soon as possible, addressed as above.

Candidates will be examined by the Examining Board in the following compulsory subjects and the highest number of marks attainable will be distributed as follows (a fee of £1 will have to be paid by each candidate to entitle him to take part in the competition): (*a*) medicine, materia medica, therapeutics and general hygiene, 1200 marks; (*b*) surgery and surgical anatomy, 1200 marks. The examination in medicine and surgery will be in part practical and will include, beyond papers, the examination of patients, the examination of pathological specimens, a knowledge of bacteriology, the performance of operations on the dead body, and the application of surgical apparatus. The attention of candidates is especially drawn to the importance of the section of Operative Surgery, as a competent knowledge in this subject is essential in order to qualify for a commission. No candidate shall be considered eligible who shall not have obtained at least *one-third* of the maximum marks in each of the above *compulsory subjects*.

Candidates may be examined in the following voluntary subjects, for which the maximum number of marks obtainable will be—Natural Sciences: chemistry (300); physiology (300); zoology (300); botany (300); and geology and physical geography (300). No candidate will be allowed to present himself for examination in more than two of these subjects. French and German (300 each), 600 marks. A number less than one-third of the marks obtainable in each of these *voluntary subjects* will not be allowed to count in favour of the candidate who has qualified in the *compulsory subjects*. The knowledge of modern languages being considered of great importance, all intending competitors are urged to qualify in French and German. The examination in chemistry will include the general principles of inorganic and organic chemistry; the preparation and properties of the chief non-metallic and metallic elements and their compounds; the preparation, properties and classification of the more important compounds, such as marsh gas, ethylene, acetylene, methyl and ethyl alcohols, glycerin, ether, formic, acetic, lactic and oxalic acids; cyanogen and cyanides; carbohydrates; fats; proteids. The examination in physiology will comprise the minute structure and functions of the various tissues and organs of the body; the physiology of the blood; the nature of food and the processes of its digestion; the mechanics of the circulation and of respiration; the physiology of nutrition, secretion, and excretion; animal heat, the nature of sensation, volition, reflex action, inhibition and influence of the nervous system on other organs and their functions. The examination in zoology will include—the general principles of biology, and a comparison of animals with plants; the distinctive characters of the larger groups of animals—the protozoa, cœlenterata, vermes, arthropoda, mollusca, echinodermata, and vertebrata—as illustrated by common types; the elements of embryology; animal parasites. The examination in botany will comprise the general principles of the morphology and physiology of low forms of life—e.g., torula, bacteria, spirogyra, moss fern; the general morphology of flowering plants; diagnosis of the important British natural orders; medicinal plants. The examination in geology and physical geography will be limited to general principles, such as: the relations of the earth to the rest of the solar system; nature of the earth's crust and the chief kinds of rocks; general configuration of land and water, mountains, plains, islands, rivers, lakes, glaciers and icebergs, ocean currents, tides, winds, storms, dew, rain, climate, volcanoes, earthquakes, distribution of animal and vegetable life.

The appointments announced for competition will be filled from the list of qualified candidates, arranged in order of merit; but should it at any time be considered expedient to grant Commissions beyond those periodically competed for, the Admiralty have power to admit annually (*a*) two candidates—proposed by the governing bodies of schools of medicine in the United Kingdom—who have satisfactorily filled the office of house surgeon in a large civil hospital for at least six months; and (*b*) not more than six candidates, according to requirements, specially recommended by the governing bodies of such colonial universities as may be selected and whose qualifications are recognised by the General Medical Council. Candidates so proposed are to be approved by the Director-General of the Medical Department of the Navy and are to be certified by the governing body proposing them as duly qualified according to the regulations in force for the entry of candidates. In cases of colonial nominations, registration of professional qualifications may be deferred until after the arrival in England of a candidate who has been passed on the station, but a Commission as Surgeon will not be granted until the certificate of the Registrar of the Medical Council has been produced at the Medical Department of the Navy. Candidates from schools at home will be required to pass a physical examination in London which will be arranged for by the Medical Director-General. Colonial candidates will have to pass a physical and test examination before a board of Naval Medical Officers on the station. Successful candidates immediately after passing the examination in London will receive commissions as Surgeons in the Royal Navy, and will undergo a course of practical instruction in Naval Hygiene, &c., at Haslar Hospital. Three prizes of the approximate value of £10 each will be awarded at the close of each session at Haslar to the students who have shown the greatest proficiency.

Surgeons on entry are only required to provide themselves with a pocket case of instruments, a stethoscope, and three clinical thermometers. All other instruments are provided at the public expense.

Promotion.

An Inspector-General of Hospitals and Fleets will be selected from amongst Deputy Inspectors-General who have in that rank three years' full pay service and who have not at any time declined foreign service except for reasons which the Lords Commissioners of the Admiralty regard as good and sufficient.

A Deputy Inspector-General of Hospitals and Fleets will be selected for ability and merit from amongst Fleet Surgeons.

(*a*) Subject to the approval of the Lords Commissioners of the Admiralty rank as Fleet Surgeon will be granted to Staff Surgeons at the expiration of eight years from the date of promotion to Staff Surgeon, provided they are recommended by the Medical Director-General and have not declined service except for reasons which in the opinion of the Lords Commissioners of the Admiralty are satisfactory. (*b*) Special promotions from the rank of Staff Surgeon to that of Fleet Surgeon will be made at their Lordships' discretion in cases of distinguished service or conspicuous professional merit. Such promotions will be exceptional and will not exceed the rate of one in two years; the total number at any one time of Fleet Surgeons holding that rank by such special promotions will not exceed six.

(*a*) Rank as Staff Surgeon will be granted, subject to their Lordships' approval, to surgeons at the expiration of eight years from the date of entry, provided they are recommended by the Medical Director-General, and have passed such examination as may be required after completion of five years from the date of entry in the rank of surgeon. (*b*) Special promotions will be made at their Lordships' discretion to the rank of Staff Surgeon in cases of distinguished service or conspicuous professional merit. Such promotions will be exceptional and not exceed the rate of one a year. The total number at any one time of Staff Surgeons holding that rank by such special promotions will not exceed eight. No officer will be so promoted unless he passes the examination prescribed for other surgeons, but in such a case the requirement of five years' time in rank of surgeon will be dispensed with. (*c*) When a surgeon's promotion to the rank of Staff Surgeon has been retarded by failure to pass the qualifying examination he will, should he pass and be promoted, be dealt with as follows. He will be granted the seniority as Staff Surgeon he would have received had he passed in ordinary course. He will reckon service for increase of full and half pay only from the date of appointment to full pay as Staff Surgeon. If on half pay, or if placed on half pay when promoted, he will receive the lowest rate of half pay of the new rank from the date of passing the qualifying examination. Where delay in passing the qualifying examination may be due to unavoidable circumstances special consideration will be given. (*d*) The seniority of surgeons on entry will be determined by the sum total of the marks they obtain at the London examination and those at the conclusion of the Haslar course and their names will then be placed in the official navy list, except in the case of candidates who hold, or are about to hold, a post as resident medical officer or surgical officer to a recognised civil hospital. These candidates will retain the position in the list which they obtained on entry, and when their period of service as resident officer is over they will join the next Haslar course and will be required to obtain qualifying marks. Surgeons entered without competition will take seniority next after the last surgeon entered at the same time by competition. (*e*) The examination for promotion to the rank of staff surgeon will be held by the Examining Board, to which a naval medical officer will be attached to conduct the examination in naval hygiene. The subjects of examination will be in writing and will include medicine, surgery, pathology, general hygiene, naval hygiene. Earlier promotion to the rank of staff surgeon may be granted to those surgeons who, before entry, have held the post of legally qualified resident medical or surgical officer to a civil hospital of not less than 100 beds for a period of not less than six months, provided their conduct and professional abilities have been favourably reported on during the time they have served in the Navy. They may be granted from six months to one year's seniority, according to the time they have held their civil appointments, but in no case will more than one year's seniority be granted. This only applies to officers who enter by competition (Para. 4 (*f*)). A candidate who at the time of passing the examination for entry into the medical branch of the Royal Navy holds, or is about to hold, an appointment as resident medical or surgical officer in a recognised civil hospital, may be allowed to serve in such civil appointment provided that the period of such service after the date of entry into the Royal Navy does not exceed one year. Pay from naval funds will be withheld from officers while thus serving, but the time concerned will reckon for increase of full and half pay while on the active list, and retired pay or gratuity on retirement or withdrawal, except that no officer will be allowed to retire on a gratuity until he has completed four years' service exclusive of the time spent as resident medical or surgical officer. The eligibility of this appointment will also be decided by the Medical Director-General.

Full Pay and Allowances.

Rank.	Daily.	Yearly.
Surgeon—	£ s. d.	£ s. d.

The medical officers in charge of the following hospitals and sick quarters will be granted charge pay: *Haslar, Plymouth, Chatham, Malta, Hong-Kong, Bermuda, Portland, Yarmouth, Haulbowline, Cape, Gibraltar, Yokohama, and Ascension.* The rate of charge pay will be as follows:—

---

[1] If any doubt should arise on this question the burden of clear proof that he is qualified will rest upon the candidate himself.

	s.	*d.*	
Inspectors-General...	10	0	a day.
Deputy Inspectors-General	7	6	
Fleet Surgeons...	5	0	"
Staff Surgeons...	2	6	"

The hospital allowances for naval medical officers at home and abroad, in lieu of provisions, for themselves and servants, and for fuel and lights, are as follows:—

—	At home.	Abroad.
	£	£
Deputy Inspectors-General	67	112
Fleet Surgeons and Staff Surgeons...	53	112
Surgeons	39	108*

* Except at Malta, where the allowance will be £70, but servants will be provided at the public expense. These allowances are also granted to medical officers of marine divisions and dockyards.

An allowance of 5*s.* a day, in addition to full pay, is granted to the senior medical officer, being a Fleet or Staff Surgeon, of a flag-ship bearing the flag of a Commander-in-Chief on a foreign station or of the Commander-in-Chief of the Channel Fleet or North America and Particular Service Squadron. An allowance of 2*s.* 6*d.* a day is granted to the senior medical officer, being a Fleet or Staff Surgeon, of the ship of a Commodore or of a senior officer commanding a foreign station. An allowance of 2*s.* 6*d.* a day may also be granted to the senior medical officer, being a Fleet or Staff Surgeon, in ships carrying the flags of flag officers or the broad pendants of Commodores not commanding stations. The following charge allowances may be granted to medical officers in charge of hospital ships: if above the rank of fleet surgeon, 5*s.* a day; and if of the rank of fleet surgeon or junior, 3*s.* 6*d.* a day. The Fleet and Staff Surgeons serving in the Admiralty and the Marine Rendezvous will be granted the Hospital allowance of £53 a year in addition to the usual lodging money. Medical officers conducting the course of instruction at Haslar Hospital will receive the following allowances: two senior officers employed upon this duty, £150 a year each; the junior officer assisting, £50 a year; and the junior officer instructing the Sick Berth Staff, £50 a year. The junior officer instructing the Sick Berth Staff at Plymouth, £50 a year Medical officers employed elsewhere than at a hospital, and not victualled in kind, receive an allowance of 1*s.* 6*d.* a day in lieu of provisions, fuel, and lights. The travelling allowances, extra pay, lodging money, and compensation for losses are fixed for naval medical officers according to their relative rank in the service.

Inspector-General	1 18 0	693 10 0

Candidates will do well to notice that the regulations issued to applicants do not put any limit on the amount of half-pay service which they may be compelled to undergo.

Retirement.

Compulsory retirement will be as follows:—

Inspector and Deputy Inspector-General of *Hospitals* and Fleets.	At the age of 60, or at any age, if he has had three years' non-employment in any one rank, or after four years' continuous non-employment in any two ranks combined. Except that if in any particular case the Lords Commissioners of the Admiralty may consider that *the interests of the* public service will be materially advanced by the further retention of an Inspector-General of Hospitals and Fleets on the active list, the age for the retirement of such Inspector-General may be extended to 62.	*To be retired* irrespective *of* age if found physically unfit for service.
Fleet Surgeon, Staff Surgeon, and Surgeon.	At the age of 55, or at any age, if he has had three years' non-employment in any one rank, or after four years' continuous non-employment in any two ranks combined.	

The special attention of candidates is directed to the following rules under which officers are allowed to withdraw from the service after four years' full pay service in the Royal Navy, with the advantage of joining the Reserve of Naval Medical Officers:—

After four years' service in the Royal Navy, an officer, if he wishes, may pass from active service to the Reserve of Naval Medical Officers, when he will reap the following advantages:—

(1) He will be granted a gratuity of £500 on passing into the Reserve.

(2) His name will be retained in the Navy List; he will retain his naval rank and be entitled to wear his naval uniform under the regulations applying to officers on the retired and reserved lists of His Majesty's Navy.

(3) If he agree to remain in the Reserve for four years he will receive a retaining fee of £25 per annum. If at the expiration of this period he agree to remain in the Reserve for a further period of four years he will continue to receive the same retaining fee.

Should an officer prefer it, however, he may simply enter the Reserve for a period not exceeding eight years, with power to give six months' notice of his intention to resign his position at any time (in which case he will receive no retaining fee). He may also adopt this method of Reserve service after the expiration of four years served under the *conditions referred to in (3), by renouncing his retaining fee for his last* four years' service in the Reserve.

No officer will be allowed to remain in the Reserve for a longer period than eight years.

Officers of the Reserve will be liable to serve in the Royal Navy in time of war or emergency. When called up for such service they will receive the rate of pay—viz., 17*s.* a day and allowances—to which they would have been entitled after four years' service on the active list.

Voluntary retirement and withdrawal will be allowed as follows. (*a*) Every officer will have the option, subject to their Lordships' approval, of retiring after 20 years' full-pay service on the scale of retired pay provided in Paragraph 16, or with a gratuity on the scale provided *in that paragraph if not eligible for retired pay.* (*b*) *At the expiration* of four, eight, 12, or 16 years' full-pay service every officer will be permitted, *subject to their Lordships' approval,* to withdraw from the Naval Service, receiving a gratuity on the scale laid down in Paragraph 16. The name of an officer so withdrawing will be removed from the lists of the Navy, with which all connexion will then be severed, except in the case of officers who withdraw after four years who are liable to serve in the Reserve. (*c*) Voluntary retirement and withdrawal at the discretion of their Lordships will be allowed, as a rule, only when an *officer is unemployed or serving* at home. Under very special circumstances, however, it may be permitted in the case of an officer serving abroad, provided he pays his successor's passage to relieve him. (*d*) Applications from officers to retire or withdraw or resign their commissions will receive every consideration, but no officer will, as a rule, be permitted to resign under three years from the date of entry.* In order that arrangements may, as far as possible, be made for the *relief of officers* who may wish to withdraw on a gratuity it is desirable that six months' notice of their wish should be forwarded for the consideration of their lordships.

* The Admiralty reserve to themselves power to remove any officer from the list for misconduct.

Gratuities and retired pay will be awarded on retirement and withdrawal on the under-mentioned scale (Paragraph 16):—

Rank.	Gratuities.	Daily.	Yearly.
	£ *s.* *d.*	£ *s.* *d.*	£ *s.* *d.*
Surgeon, Staff Surgeon, and Fleet Surgeon—			
After 4 years' full-pay service	500 0 0	—	—
After 8 years' full-pay service (including service allowed by Para. 4 (*f*)) ...	1000 0 0	—	—
After 12 years' full-pay service (including service allowed by Para. 4 (*f*)) ...	1500 0 0	—	—
After 16 years' full pay service (including service allowed by Para. 4 (*f*)) ...	2250 0 0	—	—
Fleet Surgeon—			
After 20 years' service (including proportion of half-pay time)	—	*1 0 0	365 0 0
After 24 years' service (including proportion of half-pay time)	—	*1 2 6	410 12 6
After 27 years' service (including proportion of half-pay time)	—	*1 5 0	456 5 0
After 30 years' service (including *proportion of* half-pay time)	—	*1 10 0	547 10 0
Deputy Inspector-General ...	—	1 15 0	638 15 0
Inspector-General	—	2 0 0	730 0 0

* To obtain this rate an officer must hold the commission of Fleet Surgeon.

An officer retired with less than 20 years' service on account of disability, contracted in and attributable to the Service, will receive the half pay of his rank, or, with the consent of their Lordships, a gratuity on the scales given in Paragraphs 16 and 18 (*b*), but such officer will not be entitled to receive any special compensation for the disability in addition to the gratuity as above (Paragraph 17).[2]

An officer retired with less than 20 years' service on account of disability, contracted in but not attributable to the Service, will receive—(*a*) if he has over eight years' *full-pay service*, either a *gratuity* on the scale given in Paragraph 16 or half-pay according as *their Lordships* think fit; (*b*) if he has less than eight years' *full-pay* service, such gratuity as their Lordships think fit, not exceeding the rate of £125 for each year of full-pay service (Paragraph 18). In circumstances other than those specified in Paragraphs 17 and 18, and other than misconduct, neglect of duty, &c., an officer retired with less than 20 years' service will not be allowed half pay or retired pay, but will receive a gratuity on the scale laid down in Paragraph 16 if he has eight years' full-pay service, and on that provided in Paragraph 18 (*b*) should his full-pay service not amount to eight years. The power vested in their Lordships of granting reduced rates of half pay and retired pay in cases of misconduct is extended to the award of gratuities on retirement, and the gratuity awarded will be reduced to such an amount as is thought fit. An officer retiring after 20 years' full-pay service will be eligible, if recommended by the Medical Director-General for distinguished or meritorious service, to receive a step of honorary rank, such step to be awarded at their Lordships' discretion, and not to confer any claim to increase of retired pay or of widow's pension. All retired officers will be liable, till the age of 55, to serve in time of declared national emergency, in a rank not lower than that held on retirement. This liability does not exist in cases of officers who withdraw from the Naval Service receiving a gratuity after 8, 12, or 16 years' full pay service. Retired officers will receive special consideration as regards appointments on shore connected with the Admiralty now filled by civilians.

---

[2] If the health of a surgeon breaks down before he completes 20 years' service, even if his disability be contracted in the Service or be due to *climatic causes*, he is liable at once to be placed on the retired list, receiving only a gratuity. This point should be well noted, as it is a most unjust one.

Widow's Pension.

When an officer retires or withdraws *on a gratuity* his widow and children will have no claim to pension or compassionate allowance. Officers serving in the reserve who during re-employment are injured on duty, or lose their lives from causes attributable to the service, come under the same regulations as regards compensation for themselves, or pensions and compassionate allowances for their widows and children, as officers of the same rank on the permanent Active List.

Miscellaneous.

A special cabin will be appropriated to the Fleet or Staff Surgeon or the Surgeon in charge of the medical duties in each ship. Special regulations have been made as regards the mess expenses of medical officers appointed to the several divisions of Royal Marines for limited periods. Every medical officer will be required to undergo a post-graduate course of three months' duration at a Metropolitan Hospital once in every eight years (should the exigencies of the Service permit), and this as far as possible during his Surgeon's, Staff Surgeon's, and Fleet Surgeon's period of service. While carrying out this course the medical officer will be borne on a ship's books for full pay and will be granted lodging and provision allowances and travelling expenses as for service under the Regulations to and from his home or port; the fees for each course (not exceeding £25) will be paid by the Admiralty on the production of vouchers at the end of the course. The medical officer will be required to produce separate certificates of efficient attendance in the following: (1) the medical and surgical practice of the hospital, including instruction in anæsthetics; (2) a course of operative surgery on the dead body; (3) a course of bacteriology; (4) a course of ophthalmic surgery, particular attention being paid to the diagnosis of errors of refraction; and (5) a practical course of skiagraphy. Relative rank is accorded to medical officers as laid down in the King's Regulations and Admiralty Instructions.

The Admiralty has made a considerable effort to make the Medical Service attractive to men of a good professional stamp. The new regulations promulgated on Oct. 31st, 1903, are of course included in the above account of the Naval Medical Service. By these regulations promotion was accelerated, special promotion in the lower grades was made possible in cases of distinguished service or conspicuous professional merit, and encouragement to enter the service, in the shape of earlier promotion, was given to men who have held resident posts in recognised hospitals. A feature of the latest regulations is the permission to withdraw at the end of four years with a gratuity of £500. The pay has been increased but, in respect of allowances, the medical officers of the navy, up to the senior ranks, are not as well off as those of the Royal Army Medical Corps. In spite of the steps taken by the Admiralty there is still much discontent among naval medical officers, and such discontent will exist until the medical officers are unhampered in the performance of their important work by the executive officers. The medical officers should have control over the sick bay staff in ships, and over nurses and other attendants in hospitals, and executive officers should no longer figure as presidents of "medical surveys." The authority of the Director-General must be made adequate. More care must also be taken that medical officers are assigned fitting cabin accommodation. To make the service thoroughly efficient the medical officers must be given authority and position commensurate with their responsibilities.

THE ARMY.

Consequent upon the issue of the Royal Warrant published in Army Orders dated July 1st, 1898, the Army Medical Staff and the Medical Staff Corps were formed into the Royal Army Medical Corps. Medical officers also have been placed, as regards sick leave of absence on full pay, on the same footing as that laid down for regimental officers. By a Royal Warrant dated Nov. 10th, 1891, Art. 1208*b* of the Pay Warrant was revised by inserting the words "an officer of our Royal Army Medical Corps" after the words "combatant officer," thus giving medical officers an equal title with combatant officers to reckon time on half-pay towards retirement when the half-pay has been due to ill-health contracted in the performance of military duty. Under the Royal Warrant of July, 1895, time on half-pay not exceeding a year may in similar circumstances also reckon towards promotion. In the New Royal Warrant it was announced that the late Queen had been pleased to approve of the following ranks for the officers of the Royal Army Medical Corps: Colonel, Lieutenant-Colonel, Major, Captain, and Lieutenant. The Warrant also states that the Medical Staff of the Army shall in future consist of Surgeon-Generals (ranking as Major-Generals). Officers of the Royal Army Medical Corps holding appointments in the Household Troops are to be borne as seconded officers on the establishment of the Royal Army Medical Corps.

REGULATIONS FOR ADMISSION TO THE ROYAL ARMY MEDICAL CORPS (PROMULGATED BY ARMY ORDERS DATED MAY 1ST, 1902).

A candidate for a commission in the Royal Army Medical Corps must be 21 years and not over 28 years of age at the date of the commencement of the entrance examination. He must possess a registrable qualification to practise. Candidates who are over the regulated limit of age at the date of the Examination will be permitted to deduct from their actual age any period of service in the field after Oct. 1st, 1899, that they could reckon towards retired pay and gratuity if such deduction will bring them within the age limit. A candidate must complete the subjoined form of application and declaration and submit it to the Director-General, A.M.S., in sufficient time to permit of reference to the medical school in which the candidate completed his course as a medical student.

*Application of a Candidate for a Commission in the Royal Army Medical Corps.**

1. Name in full... ... ...
2. Address ... ...
3. Date of birth † ... ...
4. Registrable qualifications ... .
5. Academic and other distinctions ... ...
6. Name of the Dean or other responsible authority of the school in which the candidate completed his course as a medical student ... ...
7. *Particulars* of any commission or appointment held in the public services ... ...
8. Date of examination at which the candidate proposes to present himself ... ...

Declaration.

(N.B.—A mis-statement by the candidate will invalidate any subsequent appointment and cause forfeiture of all privileges for services rendered.)

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief and further:—

1. That I am a British subject of unmixed European blood.

2. That I am not, as far as I know, at present suffering from any mental or bodily infirmity, or physical imperfection or disability that is likely to preclude me from efficiently discharging the duties of an officer in any climate.

3. That I will fully reveal to the Medical Board, when physically examined, all circumstances within my knowledge that concern my health.

I also declare that my vision is good with either eye (*with or without* the aid of glasses as the case may be).

Signature ....
Date..............................

---

* All communications to be addressed to the Secretary of the Army Council, 68, Victoria-street, London, S.W.

† A certificate of registration of birth or other satisfactory evidence of age, such as a declaration made before a magistrate by one of his parents or guardians, giving the date of his birth, to be furnished.

The dean of the candidate's school will be requested by the Director-General to render a confidential report as to his character, conduct, professional ability, and fitness to hold a commission in the corps and to this report special importance will be attached. A candidate whose application is regarded as satisfactory will be directed to appear before the Director-General, Army Medical Service, a few days (usually on the fourth Thursday of the month) preceding the examination. The Director-General will decide if the candidate may be allowed to compete for a commission. If approved, he will then be examined as to his physical fitness by a board of medical officers. The following is the order of the examinations:—

1. A candidate for a commission in the Royal Army Medical Corps must be in good mental and bodily health and free from any physical defect likely to interfere with the efficient performance of military duty.

2. The examination will be conducted by a board of medical officers.

3. The attention of the board will be directed to the following points: (*a*) That the correlation of age, height, weight, and chest

girth is equal or superior to that which is given in the following table:—

Physical Equivalents.

Age.	Height without shoes.	Chest.	
		Girth when expanded.	Range of expansion.
	Inches.		
21 and upwards.	62½ and under 65	35 inches.	2 inches.
	65 " 68	35½ "	2 "
	68 " 70	36 "	2 "
	70 " 72	36½ "	2½ "
	72 and upwards.	37 "	2½ "

(*b*) Measurement of height. The candidate will be placed against the standard with his feet together and the weight thrown on the heels and not on the toes or outside of the feet. He will stand erect without rigidity and with the heels, calves, buttocks, and shoulders touching the standard; the chin will be depressed to bring the vertex of the head level under the horizontal bar and the height will be noted in parts of an inch to eighths.

(*c*) Measurement of chest. The candidate will be made to stand erect with his feet together and to raise his hands above his head. The tape will be carefully adjusted round the chest with its posterior upper edge touching the inferior angles of the shoulder blades and its anterior lower edge the upper part of the nipples. The arms will then be lowered to hang loosely by the side and care will be taken that the shoulders are not thrown upwards or backwards so as to displace the tape. The candidate will then be directed to empty his chest of air as much as is possible. This is best done by continuous whistling with the lips as long as sound can be produced. The tape is carefully gathered in during the process and when the minimum measurement is reached it is recorded. He will then be directed to inflate his chest to its utmost capacity. This maximum measurement will likewise be noted. The girth with the chest fully expanded and the range of expansion between the minimum and maximum will then be recorded.

(*d*) Weight. The candidate will also be weighed and his weight recorded in the proceedings of the Board.

The regulations regarding the examination of eyesight are as follows:—

1. If a candidate can read D.=6 at 6 metres (20 English feet) and D.=0·6 at any distance selected by himself, with each eye without glasses, he will be considered *fit*.

2. If a candidate can only read D.=24 at 6 metres (20 English feet) with each eye without glasses, his visual deficiency being due to faulty refraction which can be corrected by glasses which enable him to read D.=6 at 6 metres (20 English feet) with one eye, and D.=12, at the same distance with the other eye, and can also read D.=0·8 with each eye without glasses, at any distance selected by himself, he will be considered *fit*.

3. If a candidate cannot read D.=24 at 6 metres (20 English feet) with each eye without glasses, notwithstanding he can read D.=0·6, he will be considered *unfit*. Normal vision of one eye may be sufficient to allow a higher defect in the other, to the extent of one-sixth, if the defect is simple error in refraction remedied by glasses. The candidate must be able to read the tests without hesitation in ordinary daylight. (N.B.—Snellen's test types will be used for determining the acuteness of vision.) Squint, inability to distinguish the principal colours, or any morbid conditions, subject to the risk of aggravation or recurrence in either eye, will cause the rejection of a candidate.

The following additional points will then be observed. (*b*) That his hearing is good. (*c*) That his speech is without impediment. (*d*) That his teeth are in good order. Loss or decay of the teeth will be considered a disqualification. Decayed teeth if well filled will be considered as sound. (*e*) That his chest is well formed and that his heart and lungs are sound. (*f*) That he is not ruptured. (*g*) That he does not suffer from hydrocele, varicocele, varicose veins in a severe degree, or other disease likely to cause inefficiency. A slight defect if successfully cured by operation is not a disqualification. (*h*) That his limbs are well formed and developed. (*i*) That there is free and perfect motion of all the joints. (*j*) That his feet and toes are well formed. (*k*) That he does not suffer from any inveterate skin disease. (*l*) That he has no congenital malformation or defect. (*m*) That he does not bear traces of previous acute or chronic disease pointing to an impaired constitution. *In any doubtful case the Board should further state:* (*n*) Whether he is in their opinion of pure European descent. If a candidate be pronounced physically fit for service at home and abroad he will be eligible to present himself at the next entrance examination which will be held twice in the year, usually in January and July.

The Army Council reserves the right of rejecting any candidate who may show a deficiency in his general education.

An entrance fee of £1 is required from each candidate admitted to the examination and is payable at the conclusion of his physical examination, if pronounced fit.

Candidates who have been specially employed in consequence of a national emergency, either as an officer or in a position usually filled by an officer, will be allowed to reckon such service towards retired pay and gratuity, and if over the regulated limit of age at the date of commencement of the competitive examination shall be permitted to deduct from their actual age any period of that service, if such reduction will bring them within the age limit. The duration of service is to be reckoned from the date on which the candidate commenced such service, except in the case of candidates who have served for two or more periods at short intervals. In such cases the total period of service to be considered in granting marks at the entrance examination shall be specially determined.

A candidate successful at the entrance examination will be appointed a Lieutenant on probation and will be required to pass through such courses of instruction as the Army Council shall decide and, after passing the examinations in the subjects taught and satisfying the Director-General that he possesses the necessary skill, knowledge, and character for permanent appointment to the Royal Army Medical Corps, his commission as Lieutenant will be confirmed. The commission shall bear the date of passing the entrance examination.

Before the commission of a Lieutenant on probation is confirmed he must be registered under the Medical Acts in force in the United Kingdom at the time of his appointment.

The precedence of Lieutenants among each other shall be in order of merit as determined by the combined results of the entrance examination and the examinations undergone while on probation, except that the position on the list of a lieutenant on probation, seconded to hold a resident appointment in a recognised civil hospital shall be determined by the place he has gained at the entrance examination. A lieutenant so seconded will be required, at the conclusion of his hospital appointment, to attend the course of instruction at the Royal Army Medical College; but the subsequent examinations will be of a qualifying character and will not influence his position on the seniority list of the Corps.

Lieutenants when appointed on probation will receive instructions as to the provision of uniform.

EXAMINATIONS.

Subjects for the Entrance Examination.

Candidates will be examined by the examining board in medicine and surgery. The examination will be of a clinical and practical character, partly written and partly oral, marks being allotted under the following scheme.

Medicine (written).	Maximum marks.
A. Examination and report upon a medical case	125
B. Commentary upon a case in medicine	125
(Three hours allowed for A and B together.)	
Medicine (oral).	
A. Clinical cases; clinical pathology	75
B. Morbid Anatomy and Morbid Histology...	75
(One quarter of an hour allowed for each table.)	
Surgery (written).	
A. Examination and report upon a surgical case	125
B. Commentary upon a case in surgery	125
(Three hours allowed for A and B together.)	
Surgery (oral).	
A. Clinical cases, including diseases of the eye; surgical instruments and appliances	75
(One quarter of an hour allowed for this table.)	
B. Operative surgery and surgical anatomy	75
Total marks	800

The following headings are published as a guide to candidates in drawing up their reports on cases:—(*a*) A brief history of the case as given by the patient, including such points only (if any) in the family or personal history as have a distinct bearing upon the present illness or incapacity. (*b*) A detailed account of the subjective symptoms and physical signs elicited by the candidate's personal examination of the patient, noting the absence of any which might be expected to be present in a similar case. (*c*) Where there is any reasonable doubt in the mind of the candidate as to an exact diagnosis he is to give the alternatives, with his reasons for making the selection. (*d*) A commentary upon the case as a whole, pointing out the symptoms which may be considered typical and those which appear to be unusual or only accidental complications. (*e*) Suggestions as to treatment, both immediate and possibly necessary at a later date. (*f*) A forecast of the progress and probable termination of the case.

Similarly the commentary on the report of a case submitted to the candidate should discuss: (*a*) The family and personal history and other conditions preceding the development of the condition described. (*b*) The relative significance of the physical signs, symptoms, other indications of disease noted, and the general clinical aspects of the case. (*c*) The diagnosis, with reasons for selection of the most probable, when a positive diagnosis cannot be attained. (*d*) The treatment, dietetic, medicinal, operative, &c., including a criticism of the plan adopted, and alternative schemes of treatment in case of disagreement. (*e*) The morbid appearances and an account of the post-mortem examination (if any).

The examination will be held in London and will occupy about four days.

The appointments announced for the competition will be filled up from the list of qualified candidates arranged in the order of merit, as determined by the total number of marks each has obtained. Having gained a place in this entrance examination the successful candidates will undergo two months' instruction in hygiene and bacteriology, after which they will be examined in these subjects. The maximum number of marks obtainable at this examination will be 100. It has been determined that this course shall be delivered in London and not as heretofore at Netley. A military medical staff college is now being built in London and until the new buildings are completed the instruction will be given in the laboratories of the Conjoint Board on the Thames Embankment. At the present time the professors are Major C. G. Spencer, M.B., F.R.C.S., in the department of military surgery; Lieutenant-Colonel Robert J. S. Simpson, C.M.G., in the department of military medicine; Major W. B. Leishman, M.B., in the department of bacteriology; and Lieutenant-Colonel A. M.

Davies in that of hygiene, Captain D. Harvey, M.B., and Captain C. E. P. Fowler, F.R.C.S., both of the Royal Army Medical Corps, being the respective assistant professors. Colonel H. R. James, F.R.C.S., the commandant of the Medical Staff College, instructs in hospital and corps administration, in the duties of officers on transports, and in the examination of recruits. The course of hygiene has hitherto comprised the examinations of water and air, the general principles of diet with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the consideration of the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The pathological course has up to the present time included bacteriology and demonstrations in physiological chemistry. The surgical course consists of lectures and demonstrations in military surgery and lectures on errors of refraction from a military point of view. On completion of the above course Lieutenants on probation will be ordered to proceed to the depôt of the Royal Army Medical Corps at Aldershot for a three months' course of instruction in the technical duties of the corps, and at the end of the course will be examined in the subjects taught. The maximum number of marks obtainable at this examination will be 100. A Lieutenant on probation who fails to qualify in either of these examinations will be allowed a second trial, and, should he qualify, will be placed at the bottom of the list. Should he again fail in either examination his commission will not be confirmed.

EXAMINATIONS FOR PROMOTION IN THE ROYAL ARMY MEDICAL CORPS.

These examinations are intended to test the progress and proficiency of officers in those branches of knowledge which are essential to their continued efficiency.

Lieutenant before Promotion to Captain.—(For Lieutenants appointed after March 31st, 1901.) This examination may be taken at any time after completing 18 months' service and will be held in the military district in which the officer is serving. The subjects of this examination, which are detailed in the King's Regulations, are as follows: (1) squad, company, and corps drills and exercises; (2) the duties of wardmasters and stewards in military hospitals, and the preparation of returns, accounts, and requisitions connected therewith; (3) duties of executive medical officers; and (4) military law.

Captains before Promotion to Major.—(For Captains promoted to that rank after July 27th, 1895.) Captains will be examined under the rules laid down in Paragraph 23 and will be eligible for acceleration in their promotion to the rank of Major under Article 352 of the Royal Warrant, subject to the following restrictions—(*a*) The acceleration which can be gained by a Captain promoted to that rank in January, 1896, will be limited to six months, and an officer gaining this acceleration will take precedence after the last Captain promoted Major on completion of 12 years' service. (*b*) The acceleration which can be gained by a Captain promoted to that rank in July, 1896, will similarly be limited to 12 months, and an officer gaining this acceleration will take precedence next after the last Captain promoted to that rank in January, 1896, who may have gained six months' service. (*c*) A Captain promoted to that rank in January, 1897, can gain the full acceleration but will take precedence after any captain promoted to that rank in July, 1896, who may have gained 12 months' acceleration. (*d*) Officers gaining acceleration under (*a*) will take precedence *inter se* in order as they have obtained a special certificate or passed in the first, second, or third class, and a similar course will be followed under (*b*) and (*c*). (*e*) In all other cases an officer who gains accelerated promotion will be placed for precedence after the last officer (whether subject to acceleration or not) promoted approximately 3, 6, 12, or 18 months before him.

This examination, which may be taken at any time after completing five years' service, will be held in London on the termination of a period of special study. Courses in military surgery, in x rays, and in refraction will be held by Major C. G. Spencer, M.B., F.R.C.S. The examination will consist of written papers, essays, oral and practical examinations in the following subjects, which are detailed in the King's Regulations: (1) medicine; (2) surgery; (3) hygiene; (4) bacteriology and tropical disease, and (5) one special subject from the subjoined list to which additions may from time to time be made: (*a*) bacteriology; (*b*) dental surgery; (*c*) dermatology, including venereal diseases; (*d*) midwifery and gynæcology; (*e*) operative surgery, advanced; (*f*) ophthalmology; (*g*) otology, including laryngology and rhinology; (*h*) psychological medicine; and (*i*) State medicine. Captains serving in that rank before July 27th, 1895, will be promoted under the old regulations contained in Appendix I., Regulations for Army Medical Services, and will not be eligible for acceleration.

Majors before Promotion to Lieutenant-Colonel (for Majors promoted to the rank after March 31st, 1895).—This examination, which may be taken at any time after three years in the rank of Major, will be held in the military district in which the officer is serving at times which will be duly notified. The subjects of this examination, which are detailed in the King's Regulations, are as follows: 1. Military law. 2. Army medical organisation in peace and war. 3. Sanitation of towns, camps, transports, &c. 4. The laws and customs of war, so far as they relate to the care of the sick and wounded. 5. One special subject from the subjoined list to which additions may from time to time be made: (*a*) medical history of important campaigns; and (*b*) a general knowledge of the Army Medical Services of other Powers.

PAY.

The following shall be the rates of pay, additional pay, and charge pay of the Army Medical Staff and Royal Army Medical Corps:—

Army Medical Service.	Inclusive of all allowances except field and travelling allowances (yearly).
At Headquarters.	£
Director-General	2000
Deputy Director-General	1500
Assistant Director-General	850
Deputy Assistant Director-General	750
	Exclusive of allowances (daily).
At Other Stations.	£ s. d.
Surgeon-General	3 0 0
Colonel	2 0 0
Lieutenant-Colonel	1 10 0
Lieutenant-Colonel specially selected for increased pay after at least eight years' service abroad	1 15 0
Major	1 3 6
After three years as such	1 6 0
Captain	0 15 6
After seven years' total full-pay service	0 17 0
After ten years' total full pay service	1 1 0
Lieutenant on probation and Lieutenant	0 14 0
Adjutant of the Royal Army Medical Corps (Volunteers)	The pay of his rank.

A Captain of the Royal Army Medical Corps, holding the brevet rank of Major, shall receive pay at 2*s.* a day, in addition to the rates laid down.

Additional Pay.

An officer not serving on the Headquarters Staff appointed a member of the Advisory Board, £150 a year. An officer serving as secretary of the Advisory Board and Nursing Board, £100 a year. An officer under the rank of Lieutenant-Colonel holding an appointment as specialist, 2*s.* 6*d.* daily.

Charge Pay.

(*a*) An officer in charge of a general or other hospital, or of a division of a general hospital—

	Daily. s.	d.
If in charge of at least 50 beds	2	6
" " 100 "	5	0
" " 200 "	7	6
" " 300 "	10	0
(*b*) Senior medical officer, Royal Arsenal, not exceeding	10	0
(*c*) Officer in command of the Depôt, Royal Army Medical Corps	5	0
(*d*) The Senior officer of the Army Medical Service with an army in the field— A rate to be fixed by the Secretary of State, according to the magnitude of the charge.		
(*e*) In a command abroad— The senior medical officer, if the number of soldiers is 1500 or upwards	5	0

Extra-duty Pay.

An officer of the Royal Army Medical Corps, appointed to act as adjutant or quartermaster of the Royal Army Medical Corps (Militia) during preliminary drill or training shall receive extra-duty pay at the following rates:—

	Daily. s.	d.
Acting Adjutant	2	6
Acting Quartermaster	2	0

Reserve of Officers.

An officer of our Royal Army Medical Corps with at least three, but not more than six, years' service may be permitted by the Secretary of State to become an Army Reserve Officer for a period of seven years, and while so serving he shall receive pay at the rate of £25 a year. With the sanction of the Secretary of State such officer may be allowed to return to the active list, and if the period he has been in the reserve of officers amounts to at least one year, and not more than three years, he shall be allowed to reckon one-third of such period towards promotion, gratuity, and pension.

Seconded Officers.

A Lieutenant on probation who at the time of passing the examination for admission to the Royal Army Medical Corps holds, or is about to hold, a resident appointment in a recognised civil hospital may be seconded for a period not exceeding one year during which he holds the appointment. While seconded he shall not receive pay from army funds, but his service shall reckon towards promotion, increase of pay, gratuity, and pension.

PROMOTION.

Every promotion of a medical or departmental officer shall be made with the approval of the Army Council. Promotion by selection shall be given on the ground of ability and merit, due consideration being given, however, to length of efficient service.

An officer shall be eligible for promotion to the rank of Captain on the completion of three and a half years' service, and to the rank of Major on the completion of 12 years' service, provided that in each case he has previously qualified in such manner as may be prescribed by the Army Council.

Promotion to the rank of Lieutenant-Colonel shall be made by selection from officers who have completed at least 20 years' service, and have qualified in such manner as may be prescribed by the Army Council.

If an officer has passed with distinction the examination qualifying for promotion to the rank of Major, the period of service required to render him eligible for the rank of Major or Lieutenant-Colonel may be reduced as follows:—

	Months.
If he obtained a "special certificate"	18
,, *passed in the 1st Class*	12
,, ,, ,, 2nd ,, ...	6
,, ,, ,, 3rd ,, ...	3

Promotion to the rank of Colonel shall be made by selection from Lieutenant-Colonels who have been specially selected for increased pay and from Lieutenant-Colonels or Surgeon-Lieutenant-Colonels of the Household Troops specially recommended to the Army Council for distinguished service in the field. Promotion to the rank of Surgeon-General shall be made by selection from Colonels. A Colonel may also be promoted to the rank of Surgeon-General for distinguished service in the field. In cases of distinguished service in the field a departmental officer may, with the concurrence of the Lords Commissioners of the Treasury, be promoted from any rank or class to the next above it and shall, if promoted to a rank or class having a fixed establishment, remain supernumerary in such rank or class until the occurrence of the vacancy to which in the ordinary course he would have been promoted. An officer of the Royal Army Medical Corps is eligible for promotion to brevet rank. A captain after at least 6 years' service, a Major or Lieutenant-Colonel, may be promoted to the next higher rank by brevet for distinguished service in the field or for distinguished service of an exceptional nature other than in the field. If the officer dies before the date on which the notification of his promotion for distinguished service in the field appears in the *London Gazette* the promotion shall bear the date which it would have borne had the officer not died. Distinction in original investigation or research may, in the case of officers of the Royal Army Medical Corps, be regarded as "distinguished service of an exceptional nature other than in the field." An officer who does not qualify for promotion to the rank of Captain or Major within the periods specified shall be placed on the supernumerary list until he qualifies or is retired from the service. Service on the supernumerary list shall not reckon towards promotion, increase of pay, gratuity, or pension. An officer who may in the opinion of the Army Council have been prevented, in very special circumstances, from qualifying for promotion, or who, having failed to qualify, may have been debarred from further opportunity of qualifying, may be provisionally promoted. If, however, he fails to qualify on the first available opportunity his promotion shall be cancelled and he shall be retired from the service. An officer shall reckon towards his promotion any time, not exceeding one year, during which he may have been on half-pay on account of ill-health caused by military service; and also any time not exceeding two years during which he may have been on half-pay on reduction. An officer while seconded shall continue to be eligible for selection for promotion as if he had remained on the establishment, and his service while seconded shall reckon towards such promotion.

Rank.

The Director-General of the Army Medical Service shall hold the substantive rank of Surgeon-General and shall rank in relation to combatant officers as a Lieutenant-General if recommended by the Army Council. All other Surgeon-Generals shall rank as Major-Generals in relation to combatant officers.

Retirement.

An officer of the Army Medical Service will be permitted to retire in cases in which such retirement may be deemed expedient by the Secretary of State.

Scale of Retired Pay.

	£	s.	d.
	Yearly.		
Director-General after 3 years' service in the appointment (with 30 years' service)	1125		
Under 3 years' service as Director-General and after not less than 30 years' service	875

Surgeon-Lieutenant Colonel or Surgeon-Major of the Household Troops—			
After 15 years' service...	1800		
,, 18 ,, ...	2500		

Except in the case of a Lieutenant-Colonel, an officer of the Army Medical Service, who, on voluntary retirement, has served for less than three years in the rank from which he retires, shall be entitled only to the gratuity or retired pay assigned to the next lower rank.

Retirement on Account of Age or Limitation of Period of Service.

The Director-General of the Army Medical Service shall retire on completion of the term of his appointment, and the retirement of other officers of the Army Medical Service except Quartermasters) shall be compulsory at the following ages: Surgeon-General, 60; Colonel, 57; and other officers, 55. A Major shall retire on completion of 25 years' service; or, if he fails to qualify for promotion, on completion of 20 years' service. A Lieutenant placed on the special list shall be retired if he fails to qualify at the next succeeding examination. A Captain placed on the special list shall, if he fails to qualify at the next succeeding examination, be retired at once on any gratuity for which he may be eligible, and if not so eligible shall be retired as soon as he completes five years' service in the rank of Captain. It shall be competent to the Secretary of State to place a medical officer on the retired list after 30 years' service.

Retirement on Account of Medical Unfitness.

An officer of the Army Medical Service or a medical officer of the Royal Malta Artillery placed on the half-pay list on account of medical unfitness shall, if not previously retired, be retired from the Army at the expiration of five years from the date on which he was placed on the half-pay list, or, if reported by the regulated medical authority to be permanently unfit for duty, on the officer's application, at such earlier date as may be decided by the Army Council.

An officer, whether on full pay or half pay, who, to the satisfaction of the regulated medical authority has been pronounced insane, shall be retired from the Army with the retired pay to which he would be entitled if reported by the regulated medical authority to be permanently unfit for duty. If his disability was not caused by military service and he is not entitled to permanent retired pay by length of service he shall receive temporary retired pay equivalent to the half pay and temporary retired pay, if any, which he would have received if his disability had been other than insanity.

Rates for Officers not qualified for Retired Pay on Voluntary Retirement.

If the unfitness was caused by military service retired pay equal to the half pay of his rank. If not so caused, provided the officer has at least 12 years' service, retired pay equal to the half pay of his rank for such period only, not exceeding five years from the date of the officer's retirement from the Army, after five years on half pay under Article 306, as the Secretary of State shall determine according to the merits of the case.

King's Honorary Physicians and Honorary Surgeons.

Six of the most meritorious officers of the Army Medical Service shall be named Honorary Physicians and six Honorary Surgeons. On appointment as Honorary Physician or Honorary Surgeon an officer under the rank of Colonel in the Royal Army Medical Corps may be promoted to the brevet rank of Colonel. A Lieutenant-Colonel appointed Honorary Physician or Honorary Surgeon shall receive pay at the rate laid down for a Colonel of the Royal Army Medical Corps when qualified for promotion to that rank.

Medical Officers of the Regiments of Household Troops.

Household Cavalry.

Commissions as surgeon-lieutenants in our Household Cavalry shall be given, on the nomination of the titular colonels of the regiments, to persons approved by our Army Council.

Promotion.

Household Cavalry.

A Surgeon-Lieutenant shall be eligible for promotion to the rank of Surgeon-Captain on completing three and a half years' service, and a Surgeon-Major for promotion to the rank of Surgeon-Lieutenant-Colonel on completing 20 years' service. Promotion from Surgeon-Captain to Surgeon-Major shall be by seniority on the medical establishment of the brigade, but only on a vacancy occurring for such promotion.

A Surgeon-Lieutenant, Surgeon-Captain, or Surgeon-Major of our Household Cavalry may be promoted for distinguished service in the field under the conditions laid down in Article 327.

Pay.

	Daily. £	s.	d.
Surgeon-Lieutenant-Colonel	1	10	0
Surgeon-Major	1	3	6
After three years' service as such	1	6	0
Surgeon-Captain...	0	15	6
After seven years' service	0	17	0
After ten years' service	1	1	0
Surgeon-Lieutenant	0	14	0

Promotion.

A medical officer of our Household Troops shall be eligible for extra pay under the provisions of Articles 367 and 368.

General Regulations.

In all matters not provided for by Articles 382 to 387 and 655 to 562 the medical officers of Our Household Troops shall be governed by the general regulations for regimental officers of our army.

Exchanges and Transfers.

An officer of the Royal Army Medical Corps shall be permitted to exchange with another officer of such corps, or with a medical officer of the Household Troops, under such conditions and regulations as may from time to time be made.

A medical officer of the Household Troops may be permitted to exchange with an officer of the Royal Army Medical Corps, provided that an officer exchanging into the Royal Army Medical Corps has fulfilled any conditions as to service abroad required of officers of such corps.

Exchanges between officers of the Royal Army Medical Corps under the rank of Major and medical officers of the Indian Military Forces, and transfers of such officers from either of the above services to the other, shall only be permitted subject to the approval of the Secretary of State for India in Council and on the following conditions: (1) That the officers have less than seven years' service; (2) that the senior officer exchanging takes the place of the junior on the list and shall not be promoted until the officer next above him has been so promoted; (3) that the junior officer exchanging is placed for seniority next below all medical officers whose commissions have the same date as his own; and (4) that the officer transferred is placed for seniority below all medical officers holding the same rank at the time of his transfer and shall not be promoted until the officer next above him has been promoted.

An Officer of the Royal Army Medical Corps who has exchanged or been transferred from the Indian Military Forces shall reckon, subject to the conditions of Article 364, his previous service with the said forces towards promotion, increase of pay, gratuity, and pension.

Leave of Absence.

Full pay during ordinary leave of absence for the period admissible in the case of a staff officer may be granted to a medical officer provided that no additional expense is incurred thereby.

When the periods of leave referred to in Article 457 have been exhausted or exceeded in consequence of sickness no further pay during ordinary leave shall remain due.

Sick Leave.

An officer of the Army Medical Staff or Royal Army Medical Corps may be allowed full pay during sick leave of absence on the same conditions as those laid down for regimental officers.

A regimental officer may be permitted to draw full pay for a period not exceeding one year during sick leave granted on the recommendation of the regulated medical authority, as defined in Article 1320, provided there is a reasonable probability that he will be fit to return to duty at the *expiration of his* leave.

In very special cases, such as loss of health from tropical service, active operations, or wounds, full pay may be issued for a period or periods of sick leave in excess of that laid down in Article 298, provided that the officer's sick leave shall not in all exceed eighteen months.

When a medical officer is sick at his station, whether in hospital, quarters, or lodgings, his absence from duty on account of sickness, if not exceeding 30 days in duration, and if duly certified by a medical officer, shall not be included in the period of absence on leave to which the issue of pay is limited by Article 457, provided the general officer commanding at the station considers that the circumstances of the case warrant such a concession. Any excess of such leave of absence on account of sickness at an officer's station beyond the period of 30 days shall come under the provisions of Article 458.

Service on the West Coast of Africa.

An officer volunteering for, or ordered to, the West Coast of Africa shall receive double pay while actually serving on the coast, and for any time spent at Madeira or the Canary Islands on sick leave, or on ordinary leave not exceeding 61 days in a year.

For each year's service on the coast a medical officer shall be entitled to full pay during 183 days' leave at home, and for every additional period beyond a year he shall have a proportionate extension of full pay during leave.

Each year or portion of a year served on the West Coast of Africa by an officer of the Royal Army Medical Corps shall reckon double towards voluntary retirement or retired pay, provided that he has served 12 months on the coast. In ordinary cases the 12 months may be made up of two separate periods of not less than six months each; and if an officer leaves the coast on account of sickness he may reckon any period of service on the coast, however short, in order to make up the 12 months' coast service which is required to entitle him to count his service double. Except when the officer has been invalided, any broken period, if amounting to less than six months' of service on the coast, and leave on full pay, shall not reckon double under this article.

Widows' Pensions.

Widows' pensions and compassionate allowances for children and other relatives of deceased officers are given under certain conditions specified in the Royal Warrant for Pay and Promotion. There is also an Army Medical Officers' Widows' Annuity Fund on mutual assurance principles.

Indian Medical Service.

The grades of officers in the Indian Medical Service are the same as those of the Army Medical Service and Royal Army Medical Corps. The Director-General will rank either as Major-General or Lieutenant-General as may be decided in each case by the Secretary of State for India in Council.

Regulations for the Examination of Candidates for Admission to the Indian Medical Service.

Candidates must be natural born subjects of His Majesty, of European or East Indian descent, between 21 and 28 years of age at the date of the examination, of sound bodily health, and in the opinion of the Secretary of State for India in Council in all respects suitable to hold commissions in the Indian Medical Service. They may be married or unmarried. They must possess a diploma or diplomas entitling them under the Medical Acts to practise both medicine and surgery in Great Britain and Ireland. Examinations for admission to the service usually take place twice in the year—in January and July.

They must subscribe and send in to the Military Secretary, India Office, Westminster, so *as to reach that address by the date fixed in the advertisement of the examination*, a declaration according to the annexed form.

Declaration and Schedule of Qualifications to be Filled up by Candidates.

* I ....

.... Years of Age in .... last, *vide accompanying Certificate*, a Candidate for employment in His Majesty's Indian Medical Service, do hereby attest my readiness to engage for that service, and to proceed on duty immediately on being gazetted.

I declare that I labour under no Mental or Constitutional Disease, nor *any imperfection* or disability that can interfere with the most efficient discharge of the Duties of a Medical Officer.

† I received my Medical Education and completed my course as Medical Student at..

‡ I have the Degree of A.M. or A.B. from the ....

I have the Degree of M.D. or M.B. from the ....

I have the following registrable qualifications :—..............................

....

....

(Signature at full length) ....

(Date)..

(Place of residence) ....

Candidates who desire to undergo the voluntary examination are to sign the following declaration:—

It is my intention to undergo the voluntary examination in .... §

* *Christian and surname at full length.*

† Give colleges and medical schools in full.

‡ The dates of graduations and the universities or colleges are to be stated. The candidate should state whether he has served in the medical departments of the army or navy or in the subordinate medical department in India.

§ State whether Botany or Zoology will be taken up.

This declaration must be accompanied by the following documents:—*a. Proof of age* either by Registrar-General's certificate, or, where such certificate is unattainable, by the candidate's own statutory declaration, form of which can be obtained at the India Office, supported, if required by the Secretary of State, by such evidence as he may consider satisfactory. A certificate of baptism which does not afford proof of age will be useless. *b.* A recommendation from some person of standing in society—not a member *of his own family*—to the effect that he is of regular and steady habits and likely in every respect to prove creditable to the service if admitted; and a certificate of moral character from a magistrate or a minister of the religious denomination to which the candidate belongs. *c.* A certificate of having attended a course of instruction for not less than three months at an ophthalmic hospital *or the* ophthalmic department of a general hospital, which course shall include instruction in the errors of refraction. *d.* Some evidence of having obtained a registrable qualification. *e.* In the case of natives of India or others educated in that country, in addition to the certificates referred to in paragraph 2 and paragraph 4 (*b*), (*c*), and (*d*), the candidate will be required to produce a certificate signed by the Director-General, Indian Medical Service, that he is a suitable person to hold a commission in the Indian Medical Service.

The Secretary of State for India reserves the right of deciding whether the candidate may be allowed to compete for a commission in His Majesty's Indian Medical Service.

The physical fitness of each candidate will be determined by a Board of Medical Officers who are required to certify that his vision is sufficiently good to enable him to pass the tests laid down by the regulations. Every candidate must also be free from all other organic disease and from constitutional weakness or other disability likely to unfit him for military service in India. The standard of eyesight is the same as for the Royal Army Medical Corps and the physical examination is in all respects the same (see under Royal Army Medical Corps). Candidates who pass the physical examination will be required to pay a fee of £1 before being permitted to compete. No candidate will be permitted to compete more than three times.

On proving possession of the foregoing qualifications the candidate will be examined by the Examining Board in the *following* subjects and the highest number of marks attainable will be distributed as follows:—

	Marks.
1. Medicine, including therapeutics...	1200
2. Surgery, including diseases of the eye	1200
3. Surgical anatomy and physiology	600
4. Pathology and bacteriology	900
5. Midwifery and diseases of women and children	600
6. Chemistry and pharmacy, with either botany or zoology...	600

N.B.—The examination in medicine and surgery will be in part practical and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The examination in chemistry will be limited to the elements of the science and to its application to medicine, pharmacy, and practical hygiene. No candidate shall be considered eligible who shall not have obtained at least *one third* of the marks obtainable in each of the above subjects and *one half* of the aggregate marks for all the subjects. No syllabus is issued in the subjects of botany and zoology; a general knowledge is required.

After passing this examination the successful candidates will be required to attend one entire course of practical instruction at the Army Medical School and elsewhere, as may be decided in (1) hygiene, (2) military and tropical medicine, (3) military surgery, and (4) pathology of diseases and injuries incidental to military and tropical service. This course will be of not less than four months' duration.[3]

During this period of instruction each candidate will receive an allowance of 14*s.* per diem, with quarters (where quarters are not provided, with the usual allowances of a subaltern in lieu thereof), with the usual fuel and light allowances of a subaltern, to cover all costs of maintenance, and he will be required to provide himself with uniform (viz., the regulation undress uniform and mess dress of a Lieutenant of the Indian Medical Service, as described in Indian Army Regulations, Vol. VII., with Sam Browne belt, but without the sword).

---

[3] For the present it has been arranged that two months of the course will be spent in London where the probationers will be instructed with the lieutenants on probation for the Royal Army Medical Corps in Hygiene and Bacteriology. They will attend a course of instruction in tropical medicine and military surgery at the College. In our opinion as long as the lieutenants-on-probation of the Indian Medical Service receive their instruction at the College, the post of Professor of Medicine in the College should be held by a distinguished officer of the Indian Medical Service and not as at present by an officer of the Royal Army Medical Corps who has had no training as a teacher and does not possess any special knowledge of tropical diseases. The lectures on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad, the management of lunatics under the conditions of military service, &c. The lieutenants-on-probation of both services will attend the New Millbank Hospital where they will be taught practically the details of the management of patients in a military hospital, and the registration of their diseases, the duties of invaliding, the modes of filling up the regulation statistical returns, and other service documents. No provision for instruction in lunacy has as yet been made in London. The course for the lieutenants-on-probation in London now lasts two months but it is proposed to extend it to three months and, now that the Netley course does not exist for the Indian Medical Service, the Indian probationers shall go to Aldershot for a course of drill after the completion of the instruction in London. While in London the lieutenants-on-probation for both services now reside at the St. Ermin's Hotel, Westminster. The candidate's commission as lieutenant will bear the date on which the course of instruction commences, but his rank will not be gazetted until he has passed the final examination.

A lieutenant-on-probation who is granted sick leave before the completion of his course of instruction and final admission to the service will receive furlough pay at the rate of 10*s.* 6*d.* a day for the period of his sick leave.

Candidates will be required to conform to such rules of discipline as may from time to time be laid down.

At the conclusion of the course candidates will be required to pass an examination on the subjects taught during the course of instruction.

Officers appointed to the Indian Medical Service will be placed on one list, their position on it being determined by the combined results of the preliminary and final examinations. They will be liable for military employment in any part of India, but in view to future transfers to civil employment, they will be allowed a choice, according to their position on the list above referred to, of the following civil areas:—(1) Madras and Burma; (2) Bombay with Aden; (3) Upper Provinces—i.e., United Provinces, Punjab, and Central Provinces; and (4) Lower Provinces—i.e., Bengal, and Eastern Bengal and Assam. Officers transferred to civil employment, though ordinarily employed within the area to which they may have been assigned, will remain liable to employment elsewhere according to the exigencies of the service.

The prizes formerly open to competition in the old Army Medical School at Netley have been transferred to the Medical Staff College in London and at present they are re-distributed as follows (but the arrangements as regards all the prizes are to be re-made now that all the course is to be attended in London): The Herbert Prize, the Parkes Memorial Bronze Medal, and the de Chaumont prize are now set aside to be competed for by the lieutenants-on-probation of the Royal Army Medical Corps, while the Webb prize and the Pathology prize are competed for by the young officers of both services. The two Montefiore prizes are open to the competition of the lieutenants-on-probation of the Indian Medical Service, and the Martin Memorial Gold Medal is competed for by the lieutenants-on-probation for the same service after the course in Military Medicine. The Maclean prize was withdrawn on the abolition of the Army Medical School and foundation of the Medical Staff College. The Herbert Prize of £20 is awarded to the lieutenant-on-probation who has obtained the highest number of marks at the Staff College examination in London; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in hygiene; the de Chaumont prize of books to the one who takes second place in Hygiene; the Montefiore Medal and £21 are awarded for Military Surgery; the Montefiore Second Prize, a cheque to the lieutenant-on-probation who obtains the second highest number of marks in this branch; a prize of books is given for the highest number of marks gained in Pathology; and the Marshall Webb prize of £5 and a bronze medal is awarded for Hospital Administration.

At the close of the session those lieutenants-on-probation who have obtained one-third of the possible total of marks and have satisfied the authorities that they possess the necessary skill, knowledge, and character for permanent appointment are recommended for commissions as Lieutenants in the Indian Medical Service.[4]

Officers on appointment are, when possible, provided with passage to India by troop transport; when such accommodation is not available passage at the public expense is provided by steamer, or a passage allowance granted if preferred. A charge for messing during the voyage is made at the rate of 2*s.* a day. This payment does not include the cost of liquors, which are charged for as extras. Any officer who may neglect or refuse to proceed to India under the orders of the Secretary of State for India within two months from the date of terminating his course of instruction, or within 14 days of the termination of his hospital appointment if the Secretary of State has permitted him to hold one will be considered as having forfeited his commission unless special circumstances shall justify a departure from this regulation. A lieutenant may be promoted to the rank of Captain on completing three years' full-pay service from the date of first commission, but after completing 18 months' service and before promotion to the rank of Captain he will be required to pass an examination in military law and military medical organisation, the result of which may affect his promotion. With reference to the extract from the *Gazette of India*, Medical Department, No. 1047, dated Oct. 24th, 1903, paragraph 4, it is notified that the Government of India has decided that the scope of the examination which lieutenants of the Indian Medical Service will be required to pass after completion of 18 months' service will be as follows: Subject (*h*) Text-books, the relevant portions of the Army Regulations of India, vols. ii. and vi., and the Field Service Departmental Code (Medical). Subhead (*a*) (2): The duties of the subordinate *personnel* of native military hospitals and the preparation of returns and requisitions connected therewith. Subhead (3): The duties of executive medical officers of the Indian Medical Service. Subject (*d*), subhead (2): Indian military law and Indian articles of war as laid down for officers of the Supply and Transport Corps in G.O.C.C. 897 of 1902. One paper will be set in each of subheads (2) and (3) of subject (*h*). The time allowed for each paper will be three hours. The examinations will take place at district headquarters twice annually, on March 1st and Oct. 1st, simultaneously with those for other officers, commencing on Oct. 1st, 1904. The standard required will be for a pass 5 in (*h*) and 5 in law: for special certificate 8 in (*h*) and 8 in law. An officer may present himself for examination in the above subjects either separately or conjointly. The above rules apply only to officers appointed to the Indian Medical Service on or after Jan. 31st, 1900. The names of candidates for examination will be submitted by general officers commanding districts to the Director of Military Education in India so as to reach that officer by Sept. 1st and Feb. 1st annually. Captains are promoted to the rank of Major after 12 years' full-pay service, but this promotion is accelerated by six months in the case of an officer who produces satisfactory evidence of progress in any branch of knowledge which is likely to increase his efficiency (*London Gazette*, June 28th, 1905). A Major is promoted to Lieutenant-Colonel on completion of of eight years' full-pay service in the rank of Major. All promotions to higher grades are given by selection for ability and merit. In case of distinguished service in the field a medical officer may receive substantive or brevet rank. The ages for compulsory retirement are the same as those for the Royal Army Medical Corps. Officers of the Indian Medical Service below the rank of Colonel may be granted: 1. Privilege leave under such regulations as may from time to time be in force. 2. Leave out of India for no longer period than one year, capable of extension to two years' absence from duty, on the following pay for officers in military employment (officers in civil employment are entitled to higher rates):—After arrival in India, on first appointment, £250 a year; after the commencement of the tenth year's service for pension, £300 a year; after the commencement of the fifteenth year's service for pension, £450 a year; after the commencement of the twentieth year's service for pension, £600 a year; and after the commencement of the twenty-fifth year's service for pension, £700 a year. 3. Leave in India, but for the period of one year only, on full military pay and half the staff salary of appointment. No extension of leave involving absence from duty for more than two years, whether taken in or out of India, can be granted except on specially urgent grounds and without pay. An officer unable on account of the state of his health to return to duty within the maximum period of two years' absence, unless he is specially granted an extension of leave without pay, is placed on temporary half-pay or the retired list, as the circumstances of the case may require. An officer is also liable to be placed on half-pay or the retired list should his health require an undue amount of leave, whether in or out of India. Leave may be granted at any time, but solely at the discretion of the civil or military authorities in India under whom an officer may be serving. Officers of the Administrative grades may be granted one period of leave not exceeding eight months during their tenure of appointment. Extra furlough may be granted to officers desirous of pursuing special courses of study at the rate of one month's furlough for each year's service up to 12 months in all. During such leave the ordinary furlough pay will be given with lodging allowances of 4*s.*, 6*s.* and 8*s.*

---

[4] A lieutenant who, before the expiry of one month from the date of passing his final examination, furnishes proof of his election to a resident appointment at a recognised civil hospital, may be seconded for a period not exceeding one year from the date on which he takes up such appointment, provided that he joins it within three months of passing his final examination and that he holds himself in readiness to sail for India within 14 days of the termination of the appointment. While seconded he will receive no pay from Indian funds, but his service towards promotion, increase of pay, and pension will reckon from the date on which the course of instruction for lieutenants-on-probation commences. Before the commission of a lieutenant-on-probation is confirmed he must be registered under the Medical Acts in force at the time of his appointment.

a day for Lieutenants, Captains, and field officers respectively. An officer on leave is required to join at once on being recalled to duty unless certified by a medical board as unfit to do so.

Pay and Allowances.

The rate of pay drawn by Lieutenants of the Indian Medical Service previous to arrival in India is 14s. a day, but a Lieutenant (1) who has been permitted by the Secretary of State to hold a hospital appointment will receive no pay while holding it; (2) who is detained by illness in this country will be paid at the rate of £250 a year from the date on which he would otherwise have embarked until the date of embarkation, and at the rate of 14s. a day during the voyage to India.

Pay at the above rate is issued in this country up to the date of embarkation, and an advance of two months' pay at the same rate is also made prior to embarkation, which is adjusted in India.

The following are the monthly rates of Indian pay drawn by officers of the Indian Medical Service from the date of their arrival in India:—

Rank.	Unemployed pay.	Grade pay.	Staff pay.	In officiating medical charge of a regiment.	In permanent medical charge of a regiment.
	Rs.	Rs.	Rs.	Rs.	Rs.
Lieutenant	420	350	150	425	500
Captain	475	400	150	475	550
" after 5 years' service ...	475	450	150	525	600
" after 7 years' service ...	—	500	150	575	650
" after 10 years' service ...	—	550	150	625	700
Major	—	650	150	725	800
" after 15 years' service ...	—	750	150	825	900
Lieutenant-Colonel	—	900	350	1075	1250
" " after 25 years' service ...	—	900	400	1100	1300
" " specially selected for increased pay	—	1000	400	1200	1400

NOTES.—(a) Unemployed pay is drawn by officers of less than seven years' service who are not holding officiating or substantive charge of native regiments. Officers of more than seven years' service draw grade pay alone when unemployed. Staff pay is the pay of a command and is drawn in addition to grade pay.

(b) Horse allowance is granted to officers in substantive charge of cavalry regiments at the rate of Rs. 90 a month to Lieutenant-Colonels and Majors, and Rs. 60 a month to captains and lieutenants.

Note to paras. 16 to 20.—Under present arrangements, officers of the Indian Medical Service who are not statutory natives of India receive exchange compensation allowance to compensate them for the fall of the value of the rupee. The allowance consists of an addition to their salaries (subject to certain limitations) equal to half the difference between their salaries converted at (1) 1s. 6d. the rupee, and (2) the average market rate for each quarter.

Officers holding the principal administrative appointments and substantive military charges of the Indian Medical Service receive at present the following consolidated salaries:—

		Rs. per mensem.
Surgeon-General		2200 to 3000
Colonel	from ...	1800
	to	2500

Specialist pay at the rate of Rs. 60 a month is granted to officers below the rank of Lieutenant-Colonel who may be appointed to certain posts.

The salaries of other substantive medical appointments in the Civil and Military Departments are consolidated and vary from Rs. 2000 to Rs. 450 per mensem. The pay of the majority of civil appointments has been increased, the increases in this case also being analogous to the recent increases in the pay of rank. The changes that will affect the largest number of officers are as follows: (a) The pay of civil and agency surgeons, first and second class, is fixed at Rs.50 a month more, and Rs.50 a month less, respectively, than the pay drawn by officers of the same rank in charge of native regiments. (b) Officers in charge of first- and second-class central jails will receive Rs.100 and Rs.50 respectively more than is drawn by officers of the same rank in charge of native regiments. The following new rates may also be mentioned: (a) Inspector-General of Civil Hospitals, Bengal, Rs.2500; (b) Inspector-General of Civil Hospitals, Punjab and Burma, Rs.2250; and (c) Sanitary Commissioners, Rs.1500–60–1800.

Qualified officers of the Medical Service are also eligible for appointments in the Assay Department. The salaries of these appointments are from Rs. 600 to Rs. 2250 per mensem.

Officers are required to perform two years' regimental duty in India before they can be considered eligible for civil employment.

Except in the administrative grades and in certain special appointments officers are not debarred from taking private practice as long as it does not interfere with their proper duties.

Tenure of Office in Administrative Grades.

The tenure of office of Surgeon-Generals and Colonels is limited to five years.

Colonels, if not disqualified by age, are eligible either for employment for a second tour of duty in the same grade or for employment in the higher grade of Surgeon-General by promotion thereto.

Absence on leave in excess of eight months during a five years' tour of duty involves forfeiture of appointment.

Surgeon-Generals and Colonels, on vacating office at the expiration of the five years' tour of duty, are permitted to draw *in India* an unemployed salary of Rs.1350 per mensem in the former, and Rs. 1000 in the latter case, for a period of six months from the date of their vacating office, after which they are placed while unemployed on the following scale of pay:—

—	Surgeon-General. Per diem.	Colonel. Per diem.
	£ s. d.	£ s. d.
After 30 years' service on full pay	2 5 0	1 14 0
" 25 " " "	2 5 0	1 10 0
" 20 " " " or on promotion, should this period of service not be completed...	2 0 0	1 8 0

A Surgeon-General or Colonel who has completed his term of service and has reverted to British pay may reside in Europe, at the same time qualifying for higher pension.

Retiring Pensions and Half-pay.

Officers of the Indian Medical Service will be allowed to retire on the following scale of pension on completion of the required periods of service:—

After 30 years' service for pension...	£700 per annum + £350 after three years' active employment in India as a Surgeon-General, or + £250 per annum after five years' active employment as a Colonel or £125 after three years as a Colonel. Eight months' absence on leave is allowed to count towards actual service in those grades.
" 25 " " "	£500 per annum.
" 20 " " "	£400 "
" 17 " " "	£300 "

Service for pension reckons from date of first commission and includes all leave taken under the leave rules.

Time (not exceeding one year) passed on temporary half pay reckons as service for promotion and pension, in the case of an officer placed on half pay on account of ill-health contracted in the performance of military duty.

Officers of the Indian Medical Service are liable after retirement on pension before completing 30 years' service to recall to military duty in case of any great emergency arising up to 55 years of age.

All officers of the rank of Lieutenant-Colonel and Major are placed on the retired list at the age of 55, and all Surgeons-General and Colonels at the age of 60, but the Director-General is allowed to serve until he has attained the age of 62 years. If a Lieutenant-Colonel has been especially selected for increased pay and he attains the age of 55 years before he becomes entitled to the pension of 30 years' service he may be retained until the completion of such service, and in any special case, where it would appear to be for the good of the Service that an officer should continue in employment, he may be so continued, subject in each case to the sanction of the Secretary of State for India in Council.

Officers placed on temporary or permanent half-pay are granted half-pay at the following rates.

—	Rates of Half-pay.*	
	Per diem.	Per annum.
	s. d.	£ s. d.
Under 5 years' service	6 0	109 10 0
After 5 "	8 0	146 0 0
" 10 "	10 0	182 10 0
" 15 "	13 6	246 7 6

* Officers cannot retire *in India* on half-pay (No. 45, Feb. 28th, 1865).

An officer of less than three years' service, although he may be transferred to the half-pay list under the general conditions of transfer, will not be granted any half-pay unless his unfitness has been caused by service.

Invalid Pensions

An officer who has become incapacitated for further service in India on account of unfitness caused by duty may, after he has been two years on temporary half-pay, be granted an Invalid Pension on the following scale:—

	Per annum.
After 16 years' pension service	£272
" 15 " " "	252
" 14 " " "	232
" 13 " " "	212
" 12 " " "	192

Wound Pensions.

Officers are entitled to the same allowances on account of wounds received in action and injuries sustained through the performance of military duty as are granted to combatant officers of His Majesty's Indian Military Forces holding the corresponding military rank.

Family Pensions.

The claims to pension of widows and families of officers are treated under the provisions of such Royal Warrant regulating the grant of pensions to the widows and families of British officers as may be in force at the time being.

The widows and families of officers are also entitled to pensions under the Indian Service Family Pension Regulations, for the benefits of which all officers must, as a condition of their appointment, subscribe from the date of their arrival in India.

Honours and Rewards.

Officers of the Indian Medical Service are eligible for the military distinction of the Order of the Bath and for other Orders, British and Indian, and for good service pensions. Six of the most meritorious officers are named Honorary Physicians and six are named Honorary Surgeons to His Majesty. On appointment as Honorary Physician or Surgeon an officer below the rank of Colonel is promoted to that rank, remaining supernumerary until absorbed. A retired officer appointed Honorary Physician or Surgeon to the King is granted the honorary rank of Colonel, if on retirement he had not attained to that rank.

NOTE.—The following is a list of recognised Civil Hospitals.—England and Wales.—London: St. Bartholomew's Hospital, Charing Cross Hospital, Guy's Hospital, King's College Hospital, London Hospital, Middlesex Hospital, St. George's Hospital, St. Mary's Hospital, St. Thomas's Hospital, University College Hospital, and Westminster Hospital. Birmingham: General Hospital and Queen's Hospital. Bristol: Royal Infirmary and General Hospital. Cambridge: Addenbrooke's Hospital. Cardiff: Cardiff Infirmary. Leeds: General Infirmary. Liverpool: Royal Infirmary and Southern Infirmary. Manchester: Royal Infirmary. Newcastle-on-Tyne: Royal Infirmary. Oxford: Radcliffe Infirmary. Sheffield: Royal Infirmary and Royal Hospital. Scotland.—Aberdeen: Royal Infirmary. Dundee: Royal Infirmary. Edinburgh: Royal Infirmary. Glasgow: Royal Infirmary and Western Infirmary. Ireland.—Belfast: Royal Victoria Hospital. Cork: North Infirmary and South Infirmary. Dublin: the Adelaide Hospital, the City of Dublin Hospital, the Jervis Street Hospital, the Mater Misericordiæ Hospital, the Meath Hospital, Mercer's Hospital, the Richmond, Whitworth, and Hardwicke Hospital, St. Vincent's Hospital, Sir Patrick Dun's Hospital, and Dr. Steeven's Hospital. Galway: The County Hospital and the Union Hospital.

The Royal Army Medical Corps is at the present time, we believe, a contented service, though the Director-General A.M.S. is excluded from the Army Council, before which he will, however, be summoned whenever his advice and specialist knowledge are required.

The blots on the present regulations for the Indian Medical Service are as follows:—

1. That no officer, however employed, can receive any staff allowance unless he has passed the lower standard examination in Hindustani.

2. That an officer who enters the service after his 25th birthday forfeits almost to a certainty his chance of ever reaching a higher pension than £500 per annum.

3. The order of the present Government of India that an officer of the Indian Medical Service must refer the question of the amount of his fees when above a certain low limit to the civil authority. The recent orders might necessitate the violation of professional secrecy.

4. The neglect of the rule that the office of principal medical officer to His Majesty's forces may be held by an officer of the Indian Medical Service.

We wish to draw the attention of the Secretary of State for India to the circumstance that the candidate's commission as a lieutenant in the Indian Medical Service bears the date on which the course of instruction commences in London, while the date of a commission of a lieutenant in the Royal Army Medical Corps is the day of passing the entrance examination. This is rather an important matter and is of consequence when officers meet in India. The date of commission for the Indian officers should be regulated by the same rule as is applicable to officers of the sister service.

SPECIALIST PAY FOR OFFICERS OF THE ROYAL ARMY MEDICAL CORPS AND INDIAN MEDICAL SERVICE IN INDIA.

On July 5th, 1905, the Government of India sanctioned the provisional adoption of the following rules for the granting of specialist's pay to officers of the Royal Army Medical Corps and the Indian Medical Service:—

1. Specialist pay is an allowance to officers below the rank of Lieutenant-Colonel for special sanitary or medical work done for the State which is not in the power of the ordinary medical officer to perform with the same efficiency as the specialist. It will not be a personal allowance but will be granted only to the incumbents of certain specified appointments.

2. Specialist pay will not be given to officers of the Indian Medical Service in civil employ.

3. The services of specialists are absolutely at the disposal of the Government in any way they may direct without further claim for remuneration.

4. Except in connexion with dental appointments, the duties of specialist appointments must be carried out in addition to ordinary hospital duties.

5. Officers of the Royal Army Medical Corps in India will be eligible for appointment as specialists under the qualifications laid down by the Army Council for the Royal Army Medical Corps.

6. The eligibility of an officer of the Indian Medical Service for specialist pay will be decided by the Director-General of the Indian Medical Service, whose decision will be based either on certificates of a recognised institution, or by the examination of the candidate. An officer may qualify as a specialist at any period of his service; the allowance will be admissible to any officer who is in a position actually to perform the duties for which he is given the appointment.

7. There shall be 105 appointments in India for which specialist pay at Rs. 60 a month shall be granted; of these appointments 55 will belong to the Royal Army Medical Corps and 50 to the Indian Medical Service, military branch. The selection for appointments will be made under the orders of His Excellency the Commander-in-Chief.

It does not appear probable to us that the above rules will attract many men to the rank of the so-called specialist or that the Government can regard with much esteem a status for which it can frame such regulations.

PUBLIC HEALTH.

INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE.

ENGLAND.

THE following resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," were adopted by the General Medical Council from 1902 to 1905. The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health or State Medicine; (2) every candidate shall produce evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory, British or foreign, approved of by the body granting the diploma and in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught; (3) every candidate shall produce evidence that, after having obtained a registrable qualification, he has for six months (of which at least three months shall be distinct and separate from the period of laboratory instruction) practically studied the duties, routine and special, of Public Health administration either under a whole-time medical officer of health or a medical officer of health who is also a teacher in public health in a recognised school, or in England and Wales under the medical officer of health of a county or of a single sanitary district of 50,000, or in one or more districts of 30,000 in Scotland or Ireland, or under a sanitary staff officer of the Royal Army Medical Corps having charge of an army corps, district, or command recognised by the General Medical Council, provided that the six months may be reduced to three if a candidate produces evidence that after obtaining a registrable qualification he has for three months attended a course of recognised instruction in sanitary law, sanitary engineering, vital statistics, and other subjects bearing on Public Health administration; (4) every candidate shall produce evidence that after having obtained a registrable qualification he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration; (5) the examination shall have been conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination; (6) the rules as to study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890." It was enacted by Section 18 (2) of the Local Government Act [England and Wales], 1888, that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in any county, or in any district or combination of districts with a population of 50,000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—is registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20,000 at least, or has for three years previously to August 13th, 1888, been a medical officer or inspector of the Local Government Board. With the sanction of the Local Government Board the same person may be appointed medical officer for two or more districts.

The regulations in question as to study may be procured at the office of the General Medical Council in London.

London University.—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' instruction in public health administration under the supervision of a medical officer of health, and three months' attendance on the practice of a hospital for infectious diseases.

Cambridge University.—Two examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held during the year 1906–7 in Cambridge. Each examination will consist of two parts. Part I. will begin on the first Wednesday in April and October respectively; Part II. will begin on the Monday following in April and October respectively; and each part will end on the following Thursday. Any person whose name is on the Medical Register is admissible as a candidate for this examination provided (1) a period of not less than twelve months shall have elapsed between the attainment of registrable qualification and the time when he presents himself for either part of the examination; (2) he produce evidence of having, after obtaining a registrable qualification, attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration; (3) he produce evidence of having, after obtaining a registrable qualification, attended during a period of six months on one or more courses, approved by the Syndicate, of practical laboratory instruction in Chemistry, Bacteriology, and the Pathology of those diseases of animals that are transmissible to man; (4) he produce evidence of having, after obtaining a registrable qualification, for six months (of which at least three months shall be distinct and separate from the period of laboratory instruction) been associated day by day in the duty, routine and special, of public health administration under the supervision of: (*a*) in England and Wales either the medical officer of health of a county or of a single sanitary district having a population of not less than 50,000 or a medical officer of health devoting his whole time to public health work; or (*b*) in Scotland or Ireland the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or (*c*) a medical officer of health who is a teacher in the department of public health of a recognised medical school; or (*d*) a sanitary staff officer of the Royal Army Medical Corps having charge of an army corps or district; or (*e*) in the British dominions outside the United Kingdom a medical officer of health of a sanitary district having a population of not less than 30,000 who himself holds a registrable diploma in public health. A certificate of an assistant officer of health of a county or a large sanitary district may be accepted, provided the medical officer of health of a county or district consents to the assistant officer giving such instruction. Any candidate who shall produce evidence that he has himself held an appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma shall be exempt from this regulation. A candidate who produces evidence that he has himself held, for a period of not less than three years, an appointment as medical officer of health of a sanitary district within the British dominions and having a population of not less than 15,000 shall be exempt from the provisions of paragraph (4). The provisions as to previous study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890.

The first part of the examination will comprise the following subjects. The elements of chemistry and physics: methods of chemical analysis and in particular the analysis of air and water. The laws of heat and the elements of pneumatics, hydrostatics, and hydraulics in their application to warming, ventilation, water-supply, and drainage. The geological and other conditions determining the healthiness of sites for dwellings. Sources, storage, and purification of water-supply. The elements of meteorology in relation to health. Principles of building construction in their application to dwellings, hospitals, and schools. The disposal of sewage and refuse and the general principles of sanitary engineering. Disinfectants, their chemistry and use. The chemical and microscopical examination of foods and the detection of the commoner forms of contamination. The methods of bacteriological investigation and analysis. The bacteriology of air, water, food, and soil. The general pathology of infection and of the diseases of animals that are transmissible to man. The second part of the examination will have reference to State Medicine and to the applications of Pathology and Sanitary Science, and will comprise the following subjects. Laws and Statutes relating to Public Health.[1] The model by-laws of the Local Government Board. Sanitation of dwellings, schools, factories, and workshops, and of villages and towns. Inspection of slaughter-houses, cowsheds, &c. Inspection of meat and other articles of food. General epidemiology, with special reference to the origin, pathology, symptoms, propagation, geographical distribution, and prevention of the epidemic, endemic, and other infective diseases both of temperate and of tropical climates. The methods applicable to the medical investigation of epidemics. Effects on health of overcrowding, vitiated air, impure water, polluted soils, and bad or insufficient food. Unwholesome trades and occupations and the diseases to which they give rise. Nuisances injurious or dangerous to health. The effects on health of season and climate. The principles and methods of vital statistics in relation to public health. (N.B.—The foregoing schedule is not to be understood as limiting the scope of the examination, which will include every branch of sanitary science. No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which bear upon the duties of medical officers of health.) The examinations in both parts will be oral and practical, as well as in writing. One day at least will be devoted to practical laboratory work and one day to oral and practical examination in, and reporting on, subjects connected with outdoor sanitary work. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has passed to the satisfaction of the examiners in both parts. Every candidate will be required to pay a fee of £6 6*s.* before admission or re-admission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be re-admitted to either part on payment of a fee of £5 5*s.* Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination and the courses of study in the University should be addressed to Dr. Anningson, Walt-ham-sal, Barton-road, Cambridge, Secretary to the Syndicate. Candidates who desire to present themselves for the examination must send in their applications on forms supplied for the purpose and transmit them with the fees to Mr. J. W. Clark, Registrary, University of Cambridge, for the April examination on or before March 17th and for the October examination on or before Sept. 15th. The prescribed certificate must be sent to the Registrary so as to reach him not later than 10 A.M. on March 30th and Sept. 28th respectively. Cheques should be crossed "Barclay and Co., Ltd." The fee for either part of the examination cannot be returned to any candidate who fails to present himself; but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion. Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provision (4), above mentioned. The following is a list of colleges and schools of medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the State Medicine Syndicate: The University Laboratories, Cambridge; London Hospital Medical College; St. Bartholomew's Hospital Medical College; King's College, London; University College, London; the Royal Army Medical College, London; the Victoria University of Manchester; the University of Durham Medical School, Newcastle-on-Tyne; University of Birmingham; University of Liverpool; St. Mary's Hospital Medical College; Charing Cross Hospital College; Westminster Hospital Medical School; University College, Bristol; the University of Leeds; Guy's Hospital Medical School; St. Mungo's College, Glasgow; Edinburgh University; Middlesex Hospital Medical School; Royal Southern Hospital, Liverpool; Royal Colleges, Edinburgh; Surgeons' Hall, Edinburgh; Trinity College, Dublin; Queen's College, Belfast; St. Thomas's Hospital Medical School; University College, Cardiff; University College, Sheffield; Medical School, Catholic University, Dublin; St. George's Hospital Medical School; University of Glasgow; University of Aberdeen; and Anderson's College, Glasgow.

---

[1] All candidates will be examined in the provisions of the English Statutes relating to public health, but any candidate will be given an opportunity of showing a special knowledge of other sanitary laws in operation within the British Empire, provided that, *when applying for admission to the examination, he give notice* of his desire and indicate the special law he proposes to offer.

University of Oxford.—An examination, open to all registered medical practitioners, conducted partly in writing, partly *vivâ voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £5 for each part. The names of candidates must be sent to the Secretary to the Boards of Faculties, to whom applications for any further information should be made.

University of Durham.—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor in Hygiene (B.Hy.) must be at least twenty-two years of age, registered, and a graduate in Medicine of a recognised university, and at least twelve months shall have elapsed after the date when the candidates obtained their first registrable qualification in Medicine, Surgery, and Midwifery before presenting themselves for examination. They shall spend six months at Newcastle-upon-Tyne studying Comparative Pathology, Practical Bacteriology, Outdoor Sanitary Work, Infections Diseases, Sanitary Chemistry, and Physics. They have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is 10 guineas and for the degree £6 6*s*. The examination is divided into two parts and candidates may present themselves for either part or both together at their option. Candidates for the degree of Doctor in Hygiene (D.Hy.) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a medical officer of health, and must write an essay upon some practical hygienic subject. The fee for the examination for the degree of D.Hy. is £5 and for the degree £6 6*s*. The regulations for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University, and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination and Diploma in Public Health is 10 guineas.

Victoria University of Manchester.—An examination in Public Health is held twice yearly under the following regulations: The examination is in two parts and is written, oral, and practical. Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health in the University, or in a college or medical school recognised for this purpose by the University; of having attended, after obtaining a registrable qualification, during at least six months, practical instruction in a laboratory approved by the University, the courses including Chemistry as applied to Public Health, Bacteriology, and the Pathology of those diseases of animals which are communicable from animals to man; of having, after obtaining a registrable qualification, attended for three months the clinical practice of a hospital for infectious diseases; of having, after obtaining a registrable qualification, practically studied the duties of outdoor sanitary work for not less than six months under the medical officer of health of a county or of a large urban district. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5*s*. and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3*s*. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin about the middle of January and the middle of July in each year.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health, by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University and they must, in addition, have attended a three months' course of Geology in the University. The following are the regulations for Diploma in Public Health (general conditions):—1. All candidates must be registered under the Medical Act. 2. The examinations will be held in the months of January and June and will consist of two parts. No candidate will be allowed to pass Part II. until he has passed Part I. 3. Candidates may enter for Parts I. and II. separately or at the same time. 4. The examination in each part will be written, oral, and practical. 5. Candidates intending to present themselves for either part of the examination must give notice in writing to the registrar of the University on the date prescribed in the calendar. 6. The fee for each part of the examination is £2. Admission fee to degree or diploma, £6. The conditions of admission to the examinations are identical with those recently approved by the General Medical Council.

Officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the staff College and pursued the further course of study approved by the General Medical Council in December, 1902, will be admitted to the Examination for the Diploma in Public Health, whether they have previously been students of the Birmingham School or not.

University of Leeds.—The University grants a Diploma in Public Health and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the various D.P.H. Examinations demands (1) a course of lectures on Public Health; (2) a course of instruction in Sanitary Chemistry; (3) a course of practical instruction in Bacteriology; (4) practical instruction in Infectious Diseases; and (5) practical work in Sanitation. Instruction in Bacteriology is given in the second term and in Chemistry in the third term. The other courses may be taken out at any time. Fees.—Chemistry, £5 5*s*.; Bacteriology, £5 5*s*.; Practical Sanitation, £10 10*s*.; Infectious Diseases, £5 5*s*.

University of Liverpool.—The University grants a Diploma in Public Health and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the various D.P.H. Examinations demands (1) a six months' course of practical instruction in Sanitary Science, (2) a six months' course of laboratory instruction in Chemistry and Bacteriology, and (3) practical instruction in Infectious Diseases. Fees.—Chemistry, £5 5*s*.; Bacteriology, £5 5*s*.; Practical Sanitation, £25; Tutorial Classes, £7 7*s*.; Infectious Diseases, £3 3*s*. The courses may be taken out at any time and students are allowed to work daily in the laboratories.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the Diploma in Public Health: Section 1: Candidates must be registered under the Medical Act. The examination consists of two parts. The fee for each part is £6 6*s*. A candidate intending to present himself must give 14 days' written notice to the Secretary, at the Examination Hall, Victoria Embankment, W.C. A candidate registered under the Medical Act on or before Jan. 1st, 1890, will be admissible to Part I. of the examination on producing evidence of being at least 23 years of age, and to Part II. on producing evidence of being at least 24 years of age. A candidate registered under the Medical Act after Jan. 1st, 1890, will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least 12 months; (2) of having attended, after obtaining such registrable qualification, practical instruction in a laboratory recognised by the Examining Board in England during a period of six months; and (3) of being at least 23 years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been associated day by day in the duty, routine and special, of Public Health administration during six months (of which at least three months shall be distinct and separate from the period of laboratory instruction required under Par. 2 for Part I.) under the supervision of a medical officer of health who fulfils certain conditions which can be ascertained on application to the secretary [2]; (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, after obtaining his registrable qualification in Medicine, Surgery, and Midwifery; and (3) of being at least 24 years of age.

SCOTLAND.

Edinburgh University.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh, viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. They must also give evidence that, subsequent to graduation in medicine, (1) they have during three months, which must be separate and distinct from the period of laboratory instruction, been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health administration under the supervison of (*a*) a medical officer of health recognised for this purpose by the General Medical Council; (*b*) a sanitary staff officer of the Royal Army Medical Corps, having charge of an army corps, district, or command, recognised for this purpose by the General Medical Council; (2) that they have attended during three months the practice of a hospital for infectious disease, at which opportunities are afforded for the study of methods of administration; and (3) that they have had three months' instruction in mensuration and drawing. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3*s*. for the First and £3 3*s*. for the Second B.Sc. Examinations, and £10 10*s*. for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom; and a period of not less than 12 months must elapse between medical graduation and entrance to the examination for the diploma. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University, together with having during six months (whereof three months must be distinct from the period of laboratory instruction) been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health administration under the medical officer of health of a county or large urban district. He must have regularly attended for three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. He must also have obtained practical instruction in the drawing and interpretation of plans. Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma. The diploma is conferred after an examination in Public Health held in March and July of each year. Candidates must send in their names, with the necessary fee, to the Secretary of the Medical Faculty a fortnight before the examination. The fee is £5 5*s*. The examination is conducted by specially qualified examiners appointed by the University. Candidates may enter for the whole examination at one period or they may enter for Part I. at one period and for Part II. at another and subsequent period.

The Royal College of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have been qualified for at least one year. Those qualified before 1890 do not require to produce evidence of attendance on any special courses. All other candidates must have attended, after qualifying, six months' practical instruction in a recognised laboratory or laboratories, and must have studied for six months the duties of outdoor sanitary work under the medical officer of health of a county or large urban district or a medical officer of health who is also a teacher of Sanitary Science in a Medical School, or a sanitary staff officer of the Royal Army Medical Corps having charge of an Army Corps District or command. There are two examinations, and candidates may enter for both at one period or for either separately. The First Examination includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics, and (*c*) Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. James Robertson, solicitor, 54, George-square, and for Glasgow Mr. Alexander Duncan, LL.D., 242, St. Vincent-street.

IRELAND.

Royal University of Ireland.—This University grants a Diploma in Public Health. It is conferred only on graduates in Medicine of the University. Candidates are not admitted to this examination until the lapse of 12 months from the time of obtaining the M.B., B.Ch., B.A.O. degrees; they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2, at least one month previously to the examination. Candidates are required to produce a certificate of having, after obtaining the degrees of M.B., B.Ch., B.A.O., attended six months' practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district. Candidates at this examination must answer in the following subjects: (1) Physics, (2) Chemistry, (3) Meteorology, (4) Sanitary Engineering and Architecture, (5) Bacteriology, and (6) Hygiene, Sanitary Law, and Vital Statistics.

University of Dublin.—The Diploma in Public Health is conferred, after examination, on the following conditions. The candidate must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge. The name of the candidate must have been on the Medical Register at least 12 months before the examination. The candidate must have completed (unless registered as a practitioner on or before Jan. 1st, 1890), subsequently to registration, six months' practical instruction in a chemical and bacteriological laboratory or laboratories approved by the University, must have studied practically outdoor sanitary work for six months under an approved officer of health (at least three months of this period being distinct from the time spent in laboratory work), and must have spent three months in a fever hospital where opportunities are afforded for the study of methods of administration. The subjects of examination will be:—Part I.: Chemistry, Bacteriology, Hygiene, Pathology (including methods of post-mortem examinations), Physics, and Meteorology. Part II.: Hygiene and Epidemiology, Vital Statistics, Public Health Acts, and Sanitary Engineering and Reports.

---

[2] Provided that the period of six months may be reduced to a period of three months (which shall be distinct and separate from the period of laboratory instruction required under Regulation 2) in the case of any candidate who produces evidence that after obtaining a registrable qualification, he has during three months attended a course or courses of instruction in sanitary law, sanitary engineering, vital statistics, and other subjects bearing on public health administration given by a teacher or teachers in the department of public health of a recognised medical school.

Royal College of Physicians and Royal College of Surgeons in Ireland.[1]—Stated examinations for the Diploma in Public Health are held in the months of February, May, and November. A special examination for the diploma may, at the discretion of the Committee of Management (except during the months of August and September), be obtained on payment of £10 10*s.*, in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination. Every candidate for the Diploma in Public Health must be a registered medical practitioner. (Candidates registered or entitled to be registered prior to January, 1890, are exempt from the rules as to study.) He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months practically study outdoor sanitary work under a medical officer of health and shall as an additional requirement attend a hospital for infectious diseases. Candidates are examined on four days, commencing on the first Monday of February, May, and November. Each candidate must return his name to the secretary of the Committee of Management under the Conjoint Scheme two weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh. The fee for the examination is £10 10*s.* The examination for the diploma in State Medicine comprises the following subjects:—State Medicine and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Law, and Bacteriology. For further particulars apply to the Secretary, Committee of Management; Office, Royal College of Physicians, Dublin.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory; and, this having been attained, it is but little trouble to pass the special examinations. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns; Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than two years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital). The Dental Schools in London are the Royal Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School. Most of the large provincial towns have now dental hospitals. A convenient arrangement by which the M.R.C.S., L.R.C.P., and L.D.S. can be taken is as follows:—The Preliminary Examination in General Education having been passed the student should commence his mechanical training at a dental school or with a qualified dentist and register as a dental and medical student. (This instruction, however, may be taken prior to the date of registration as a dental student.) During his mechanical training the student should receive instruction in Chemistry and Physics, Pharmacy and Elementary Biology, and pass in these subjects before entering the hospital. (The foregoing constitute the First Examination.) Having entered the hospital the student should attend the dental and general courses contemporaneously, and pass at the end of the second winter the Second Examination—namely, Anatomy and Physiology. At the completion of his second year of study the Dental Examination should be passed. The student should then devote his time to general studies and pass the Third Examination. When time permits it is advisable to attend the general hospital only until after the First and Second Examinations have been passed. At this point a break may be made to admit of the completion of the dental curriculum and the passing of the examinations for the L.D.S. diploma. The best course, however, is entirely to finish the curriculum for the M.R.C.S. and L.R.C.P. and then take the special Dental work. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College. The L.D.S. can also be obtained alone.

REGISTRATION OF DENTAL STUDENTS.

The registration of dental students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Students who commenced their professional education by apprenticeship to dentists entitled to be registered or by attendance upon professional lectures before July 22nd, 1878 (when dental education became compulsory), are not required to produce evidence of having passed a Preliminary Examination. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies and of having received three years' instruction in mechanical dentistry from a registered practitioner. The three years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student, but no year of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

It is now necessary for anyone practising Dental Surgery in this country to be on the Register and no foreign qualifications are admitted.

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination.—Before admission to this examination the candidate must produce a certificate of having received instruction (which may be taken prior to the date of registration as a dental student) at a recognised institution in Chemistry, Physics, and Practical Chemistry. The examination consists of these subjects and is identical with Part I. of the First Examination of the Examining Board in England. II. The First Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of mechanical dentistry, under the instruction (which may be taken prior to registration as a dental student) of a competent practitioner or under the direction of the superintendent of the mechanical department of a recognised dental hospital. 2. Of registration as a dental student by the General Medical Council. 3. Of having attended at a recognised Dental Hospital and School (*a*) a course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy; (*c*) a course of Lectures on Dental Mechanics; and (*d*) a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns. Candidates may present themselves for the First Professional Examination on production of the required certificates. The Examination consists of Mechanical Dentisty and Dental Metallurgy, the examination in Dental Metallurgy being by written paper. III. The Second Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a dental student.

---

[1] No returns.

2. Of having attended at a recognised dental hospital and school (*a*) a course of Dental Anatomy and Physiology; (*b*) a separate course of Dental Histology, including the preparation of microscopical sections; (*c*) a course of Dental Surgery; (*d*) a separate course of Practical Dental Surgery; (*e*) a course of not less than five lectures on the Surgery of the Mouth, which lectures may be given at a dental hospital or at a recognised medical school; in the latter case they may form part of the course of lectures on Surgery; (*f*) a course of Dental Materia Medica; and (*g*) a course of Dental Bacteriology. 3. Of having attended at a recognised dental hospital or in the dental department of a recognised general hospital the practice of Dental Surgery during two years. 4. Of having attended at a recognised medical school (*a*) a course of lectures on Anatomy, (*b*) a course of lectures on Physiology, (*c*) a separate Practical Course of Physiology, (*d*) a course of lectures on Surgery, and (*e*) a course of lectures on Medicine. 5. Of having performed Dissections at a recognised medical school during not less than 12 months. 6. Of having attended at a recognised hospital the practice of Surgery and Clinical Lectures on Surgery during two winter sessions. 7. Of being 21 years of age. The certificates of professional study will be required to show that students have attended the courses of professional study to the satisfaction of their teachers. Candidates may present themselves for the Second Professional Examination after the completion of four years' professional study from the date of registration as a dental student and after the lapse of not less than six months from the date of passing the First Professional Examination. The Second Professional Examination consists of: Part I., General Anatomy and Physiology, General Surgery and Pathology; Part II., Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. The written examination in Part I. comprises General Anatomy and Physiology, General Pathology and Surgery, and in Part II., Dental Anatomy and Physiology, and Dental Pathology and Surgery. At the Practical Examination candidates may be examined (*a*) on the treatment of Dental Caries and may be required to prepare and fill cavities or to do any other operation in Dental Surgery (candidates must provide their own instruments); (*b*) on the Treatment of the various irregularities of Children's Teeth. There is also an Oral Examination. Candidates may take the two parts of the examination together or separately. Candidates must pass Part I. before proceeding to Part II. If they fail in Part I. they are not allowed to proceed with Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in medicine or surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and Universities above mentioned. The fee for the diploma is 20 guineas and is payable as follows:—Preliminary Science Examination, 3 guineas; First Professional Examination, 2 guineas; Second Professional Examination, 5 guineas; the balance to be paid on the completion of the Examinations. The Preliminary Science Examination is held in January, March, or April, July, and October in each year. The First and Second Professional Examinations are held in May and November in each year. Candidates must give 21 clear days' notice of their intention to present themselves for examination.

Royal College of Surgeons, Edinburgh.—For the Licence in Dental Surgery all candidates must pass a Preliminary Examination in General Knowledge and have their names inscribed in the *Register of Dental Students* of the General Medical Council. A copy of regulations giving a list of Preliminary Examinations recognised for obtaining this Licence, as well as of the subjects of the Professional Examinations, may be obtained from Mr. James Robertson, Clerk to the Royal College of Surgeons, at 54, George-square, Edinburgh. Students who commenced their professional education by apprenticeship or attendance on lectures before July 22nd, 1878, are exempt from the Preliminary Examinations. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates who have commenced their studies before Oct. 31st, 1898, must have attended the following curriculum: Anatomy, one course of six months; Practical Anatomy, twelve months; Chemistry, one course of six months; Practical Chemistry, one course of three months; Physiology, one course of six months; Materia Medica, one course of three months; Surgery, one course of six months; Medicine, one course of six months; and attendance on the practice of a recognised general hospital, with Clinical Instruction on Surgery and Medicine, twelve months. These courses must have been attended at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery. In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction: Dental Anatomy and Physiology (Human and Comparative) (not less than 24 lectures), Dental Surgery and Pathology (not less than 20 lectures), Dental Mechanics (not less than 12 lectures)—one course each; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Certificates of attendance on such of these courses of the new curriculum as may be respectively required will entitle candidates to appear either for the First Dental Examination or for the First and Second Examinations for the Triple Qualification, as they may select, and subject to the existing regulations for each qualification. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. *First Professional Examination*: The candidate must have attended the courses on Anatomy, Chemistry, and Physiology. The examination embraces Anatomy, Chemistry, and Physiology. The fee for those candidates who began study before Oct. 1st, 1896, is £4 4*s.* Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £6 6*s.* The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics with Dental Metallurgy. Unsuccessful candidates will be repaid £2 2*s.* in the First and £3 3*s.* in the Second Examinations. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £10 10*s.* payable for the dental diploma, of which £3 3*s.* will be returned in case of rejection. The fee payable by candidates who began study after Oct. 1st, 1896, shall be £15 15*s.*, £5 5*s.* of which are payable on entering for the First Examination and £10 10*s.* on entering for the Second Examination.

Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh. Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry. Candidates can enter for the First Examination in two divisions, the first embracing Physics and Chemistry, and the Second Anatomy and Physiology. There is a practical Examination in Mechanical Dentistry and also an examination in Practical Dentistry conducted in a dental hospital.

Royal College of Surgeons in Ireland.—All information concerning the licence in Dental Surgery may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined. The bank receipt for fees, together with all certificates, &c., are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental. Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the College. Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons on the third Wednesdays in March and September. Primary Dental Examination.—Fee £10 10*s.*; for re-examination, if rejected, £5 5*s.* Every candidate[1] is required, before admission to the Primary Dental Examination, to produce evidence—(1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses: Lectures on Practical Anatomy, including Dental Anatomy, six months; Demonstrations and Dissections, two courses of six months each; Lectures on Chemistry, six months; Lectures on Physiology, including Dental Physiology, six months; Practical Histology; and Practical Chemistry, including Metallurgy, three months; (3) of having attended Clinical Instruction at a recognised general hospital for one year. The subjects of this examination are: (1) Physics;[2] (2) Chemistry, including Metallurgy; (3) Anatomy; (4) Physiology and Histology; and (5) Surgery. Final Examination.—Candidates holding L.R.C.S.I. or students who have passed Primary Dental or Third Professional Examination of the College, £10 10*s.*; re-examination, £5 5*s.* Fees for Final Examination of all other candidates, £26 5*s.*; re-examination, £10 10*s.* Extra fee for Special Examination, £5 5*s.* Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended: (1) the following courses of lectures recognised by the College: Dental Surgery and Pathology (two courses), Dental Mechanics (two courses); (2) for two years the practice of a dental hospital recognised by the College or of the dental department of a general hospital so recognised; (3) of having been engaged during four years in professional studies; and (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended: (1) one course of Lectures on Dental Surgery and Pathology; (2) one course of Lectures on Dental Mechanics; (3) for one year the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work); and (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist. The following are the subjects of examination: Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative; Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the Workshop). Examinations for the Licence in Dentistry *sine curriculo*: The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register published under the direction of the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application.

TEACHING INSTITUTIONS.

ENGLAND.

Royal Dental Hospital of London and School of Dental Surgery, Leicester-square.—The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the mechanical training recognised by the curriculum. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory. Two scholarships of the value of £20—the Saunders and the Entrance. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Robert Woodhouse Prize of £10 is for Practical Dental Surgery. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. A prize of the value of 5 guineas is given by Messrs. Ash and Sons for the best essay on some surgical subject connected with Dental Surgery. Consulting Physician: Sir Richard Douglas Powell, Bart. Consulting Dental Surgeons: Mr. T. Arnold Rogers, Mr. Morton Smale, and Mr. C. S. Tomes, F.R.S. Dental Surgeons: Mr. J. F. Colyer, Mr. C. F. Rilot, Mr. H. Lloyd Williams, Mr. W. H. Dolamore, Mr. G. Hern, and Mr. J. G. Turner. Assistant Dental Surgeons: Mr. N. G. Bennett, Mr. D. P. Gabell, Mr. A. Hopewell Smith, Mr. H. Austen, and Mr. R. McKay. Anæsthetists: Dr. Dudley Buxton, Dr. R. J. Probyn-Williams, and Mr. H. Hilliard. Demonstrators: Mr. E. F. Ackery, Mr. H. C. Jones, Mr. A. L. Whitehouse, Mr. H. W. Perkins, Mr. L. C. Ball, and Mr. J. G. Atkinson-Fairbank. Lecturers:—Dental Anatomy and Physiology (Human and Comparative): Mr. A. Hopewell Smith. Dental Surgery and Pathology: Mr. J. G. Turner. Mechanical Dentistry: Mr. W. J. May. Metallurgy in its application to Dental Purposes: Mr. P. Ellis Richards. Dental Bacteriology: Mr. Howard Mummery. Dental Materia Medica: Mr. H. A. Austen. During the sessions the surgeons of the day will give demonstrations at stated hours. The house surgeons attend daily while the hospital is open. Fee for two years' hospital practice required by the curriculum, including lectures, £53 3*s.* in one payment, or £55 13*s.* in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £60. Both hospitals can be attended simultaneously. The fee for the instruction in Mechanical Dentistry and the two years' hospital practice required by the curriculum is £150 if paid in one instalment, or 150 guineas if paid in three equal instalments. The fee for tuition in Mechanical Dentistry is 60 guineas per *annum*. The Dean attends at the hospital every Wednesday morning from 9 to 10.30, or he can be seen at other times by appointment. *Letters to be addressed*—The Dean, 32, Leicester-square, "to be forwarded."

National Dental Hospital and College.—Corner of Great Portland and Devonshire-streets, W.—Consulting Physician: Sir Victor Horsley. Consulting Dental Surgeon: Mr. Sidney Spokes. Visiting Physician: Dr. James Maughan. Visiting Surgeon: Mr. E. W. Roughton. Dental Surgeons: Mr. F. H. Weiss, Mr. K. W. Goadby, Mr. W. Weiss, Mr. Rushton, Mr. H. J. Relph, Mr. S. F. Rose, and Mr. A. E. Relph. Assistant Dental Surgeons: Mr. H. R. Pring and Mr. H. Creemer Cooper. Anæsthetists: Mr. H. P. Noble, Mr. C. J. Ogle, Mr. Vivian B. Orr, Dr. J. Maughan, Dr. Kenneth Steele, and Dr. Cecil Hughes. Lecturers (winter), Dental Anatomy and Physiology: Dr. J. W. Pare, Tuesdays and Thursdays, 5 P.M., in October, November, and December. Dental Metallurgy: Mr. Hugh Candy, Tuesdays, 5 P.M., in January, February, and March. Dental Mechanics: Mr. H. Rose, Wednesdays, 5.30 P.M., in May,

---

[1] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries.

[2] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

June, and July. Dental Materia Medica: Mr. Charles W. Glassington, Tuesdays, 6 P.M., October, November, and December. Summer—Dental Surgery and Pathology, Mr. H. J. Relph, Thursdays, 5 P.M., during January, February, and March. Bacteriology of the Mouth: Mr. K. W. Goadby, Tuesdays, 4 P.M., during May, June, and July. Practical courses to comply with the R.C.S. curriculum are also held. The hospital is lighted throughout by electricity and warmed and ventilated by approved methods. Clinical Lectures and Demonstrations are given from time to time, and each student on entering passes through a preliminary course under a demonstrator. The stopping rooms have accommodation for 50 chairs. Dresserships in the extraction and stopping rooms are re-arranged every three months. Two Entrance Exhibitions, of the value of £40 and £20, are open for competition. Prizes are open for competition at the end of each course of lectures. Certificates of honour are also open in each class. The Rymer Medal for General Proficiency, value £5, is awarded annually to the most meritorious student; and the Ash Prize, value £3 3*s.*, for a Thesis on a subject in Dental Surgery. Total fee for the Special Lectures and Hospital Practice required, 40 guineas. A composition fee covering the two years' mechanical pupilage and the two years' hospital practice required by the Royal College of Surgeons will be arranged. Single Courses: Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Mechanics, Dental Metallurgy, Bacteriology of the Mouth, Dental Materia Medica, Demonstration of Dental Mechanics, £5 5*s.* each. Hospital Practice to registered practitioners by special permission of Committee, 12 months, £15 15*s.* The Committee also consider applications from medical men who may desire to attend the Anæsthetic Room for a course of instruction in Nitrous Oxide administration. Information respecting the Hospital Practice and the College may be obtained from the Dean, Mr. Sidney Spokes, who attends at the Hospital, Great Portland-street, on Tuesday *mornings.*

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. *The Extraction Rooms:* Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dressers. Such cases as are suitable for conservative treatment are transferred to the conservation room, taking with them a dental chart to indicate the treatment required. *The Conservation Room:* This room is open from 9 A.M. till 5 P.M. There are 55 Morrison chairs, each fitted with a saliva ejector, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon in the week to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. Dental students have the opportunity of attending concurrently at this hospital the two courses of instruction required by the examining board for the L.D.S. Eng., viz., the special lectures and practice of the Dental Department and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Two Entrance Scholarships in Dental Mechanics of the value of £20 each are offered for competition annually, one in September and one in April, and prizes of the aggregate value of £35 are awarded for general proficiency and skill in Practical Dentistry. Dental students are eligible for admission to the Residential College and enjoy the other social privileges of students in the Medical School.

Staff. — Dental Surgeons: Mr. F. Newland-Pedley, Mr. W. A. Maggs, and Mr. Wynne Rouw. Assistant Dental Surgeons: Mr. H. L. Pillin, Mr. M. F. Hopson, Mr. J. B. Parfitt, and Mr. J. L. Payne. Demonstrators of Practical Dentistry: Mr. E. B. Dowsett, Mr. P. S. Campkin, Mr. F. J. Pearce, Mr. J. E. Spiller, and Mr. H. P. Aubrey. Anæsthetists: Dr. H. F. Lancaster, Mr. C. J. Ogle, Mr. P. Turner, Mr. H. T. Hicks, Mr. A. R. Thompson, and Mr. W. M. Mollison. Lecturers.—Dental Surgery and Pathology: Mr. Wynne Rouw. Dental Anatomy and Physiology: Mr. Maggs. Operative Dental Surgery: Mr. Parfitt. Dental Mechanics: Mr. Payne. Practical Dental Mechanics: Mr. Pillin. Dental Materia Medica: Dr. A. P. Beddard. Dental Bacteriology: Dr. Eyre. Dental Microscopy: Dr. Hertz and Dr. Cameron. Metallurgy: Dr. J. Wade. Practical Dental Metallurgy: Mr. Hopson. Curators of Dental Museum: Mr. Payne and Mr. Dowsett. Dean: Dr. Eason.

London Hospital.—Mr. Dolamore and Mr. Farmer give practical instruction during the winter and summer sessions on Tuesdays and Thursdays at 11 A.M. In selecting from candidates for the office of Dental Assistant priority will be given to those who have attended the greatest number of lectures on Dental Pathology and Surgery, and have also been the most punctual in attendance in the dental department. A class for special instruction in filling teeth will be formed each term. Dental patients in 1905, 9138.

University of Birmingham.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that the students may fully qualify themselves for the Dental diploma of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum and Laboratory. An Entrance Exhibition, value £37 10*s.*, is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A.* In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the Courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Chemistry and Practical Chemistry, (*b*) Physics and Practical Physics, (*c*) Elementary Biology, (*d*) Anatomy and Practical Anatomy, and (*e*) Physiology and Practical Physiology. *B.* That he has attended the following courses and passed the class examinations in each of these subjects: (*f*) One Special Course of Lectures on Medicine, (*g*) One Special Course of Lectures on Surgery, and (*h*) Pathology and Bacteriology. *C.* That he has attended Courses and passed the class examinations in: (*k*) Dental Histology and Patho-Histology, (*l*) Comparative Dental Anatomy, and (*m*) Dental Surgery and Prosthetic Dentistry. *D.* That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D.* 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work and investigations in some subject connected with Dentistry, which thesis shall be submitted to examiners to be nominated by the Dental Advisory Board. The degree will be awarded or withheld according to the report of these examiners. 8. The University also grants a diploma in Dental Surgery (L.D.S.) to candidates who have followed the prescribed regulations for the same.

University College, Bristol. — Dental students can enter for the full curriculum at Bristol. The Lectures are delivered at the College. Practical instruction is given at the *Royal Infirmary* by Mr. Ackland and at the *General Hospital* by Mr. Genge, both institutions being recognised by the Dental Board of the Royal College of Surgeons of England. Full information may be obtained of the Dean of the Medical Faculty, Professor Edward Fawcett, University College, Bristol.

University of Manchester.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S.

Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given during the Winter and Summer sessions both at the University and at the Victoria Dental Hospital in Devonshire-street. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department and for them a separate laboratory for Practical Anatomy and common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 60 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. The composition fee for candidates for the University Diploma in Dentistry is 55 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. The composition fee for candidates for the L.D.S. of England is 60 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The payment of any of the above composition fees will entitle the student to attend all the classes in the following list which are required for their respective examinations. The composition fee does not include the hospital fees, the examination fees, the fee for the conferment of the degree or the diploma, the registration fee, nor the fees for chemicals and chemical apparatus (£1 15s.).

University of Leeds.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery are required to have passed the Matriculation examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the da'e of passing Parts I. and II. of the first examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. All candidates are required to have passed the following examinations: the first examination, the second examination, and the final examination. Each examination will include practical work in the subjects offered. All candidates are required, before presenting themselves for examination, to furnish to the registrar certificates testifying that they have attended the prescribed courses of instruction in accordance with the regulations of the University in each of the subjects which they offer, and that they have fulfilled the other requirements of the ordinance and regulations in respect of such examination. Candidates for the diploma in Dental Surgery are required to present certificates showing that they have attained the age of 21 years, that they have attended courses of instruction, approved by the University, extending over not less than four years, and that they have completed a pupilage of three years, two of such years at least having been taken before the First Professional examination. Candidates are required to satisfy the examiners in the several subjects of the following examinations: A preliminary examination in Arts; a preliminary examination in Science; the First Professional examination; and the Final examination. The classes in the Department of Dentistry will begin on Oct. 1st. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology will be given at the University in College-road. The classes in the other subjects and the systematic courses in Dental subjects will be held in the School of Medicine of the University in Thoresby-place. The systematic instruction in the School of Dentistry will be given by the following:—Anatomy: Professor T. W. Griffith. Physiology: Professor de B. Birch. Pathology: Professor A. S. Grünbaum. Medicine: Professor A. G. Barrs. Surgery: Professor H. Littlewood. Dental Surgery: Mr. A. G. G. Plumley. Operative Dental Surgery: Mr. T. S. Carter. Dental Anatomy and Physiology: Mr. A. Alan Forty. Dental Mechanics: Mr. C. Rippon. Dental Metallurgy: Mr. W. Lowson. Dental Materia Medica: Mr. J. H. Gough. The clinical instruction will be given in the Dental Department of the Leeds Public Dispensary, which is recognised by the University and by the Royal College of Surgeons. Applications for the prospectus should be made to the Dean of the Faculty of Medicine.

University of Liverpool (Liverpool Dental Hospital and School of Dental Surgery).—The University grants a diploma in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes' walk from the Dental Hospital. The two institutions are now closely associated and the management of the curriculum is in the hands of a joint committee. At the Dental Hospital recent alterations have been made, and as it now stands this school offers advantages to students which are not excelled anywhere. The ground floor of the building contains the following: Extraction room, with all needful appliances; anæsthetic room, specially reserved, with every convenience; and large waiting-room for patients. The first floor has a large board-room and a very comfortable students' room set apart exclusively for the use of students. The whole top floor of the building has been thrown into one fine, airy, and well-ventilated operating room. This room will accommodate upwards of 30 operating chairs, which are of the "Morrison pattern," and each of which has a special electric light suspended before it. In the basement a very convenient workroom has been fitted up containing the necessary requirements, and there are commodious lavatories for students. A new Laboratory for practical mechanical work has also been constructed so as to meet the requirements of the curriculum It is adequately furnished with all the modern appliances of a dental workshop. A skilled dental mechanic has been engaged and students are able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lecture at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. The staff of the hospital includes 12 honorary Dental Surgeons, a Demonstrator, two Anæsthetists, two House Surgeons, and a Curator. Fees for two years' hospital practice, £21. Apprenticeship.—A limited number of apprentices are admitted annually. Fees for three years, £105. Further information may be had from the Warden, Mr. W. H. Gilmour. The various medical and dental lectures are given at the University of Liverpool. The Anatomical Department has been removed to a new building, comprising a spacious dissecting room and a museum which contains an excellent collection of skulls illustrative of human and comparative dental anatomy. Fees: The composition fees are as follows: Diploma course (L.D.S.): Chemistry and Physics, £11 11s.; all other lectures, £50 in two instalments. Degree course (B.D.S.): £67 10s. for all lectures (including Chemistry, Physics, and Zoology) in three instalments. Two years' dental hospital, £21; general hospital practice, £10 10s.; three years' mechanical instruction (pupilage), £105.

Devon and Exeter Dental Hospital, 24, Southernhay, West, Exeter.—Established 1880.—The hospital is open daily (Sundays excepted) and patients are admitted between the hours of 9 and 11 A.M. Students attending the practice of the hospital must consider themselves strictly under the control of the medical officers and must not undertake any operation without the consent of the dental surgeon for the day. Hon. treasurer, Mr. J. M Ackland; hon. secretary, Mr. Henry Yeo.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in a spacious and well-equipped building at 31, Chambers-street and offers special advantages to dental students. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. For the special classes, both theoretical and practical, required by dental students the directors have secured the services of an efficient staff of dental officers and lecturers. There will also be a course of demonstrations in Mechanical Dentistry. Students will receive instruction in Practical Dental Mechanics under the mechanician. The fee for clinics in gold filling is included in the Dental Hospital fee of £15 15*s*. The minimum cost of classes for the whole course of dental instruction amounts to £90 7*s*. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow is recommended. The minimum cost of the Professional Education Triple Qualification and Licence in Dental Surgery amounts to £169 7*s*. The mechanical department is large and airy and furnished with all modern tools and appliances. The winter session commences Oct. 1st. The Museum is open to students for study. Further particulars can be obtained from the Dean, Mr. W. Guy.

Incorporated Dental Hospital and School, Glasgow.—The winter session will begin in October and the lectures will be delivered as follows. In Dental Mechanics on Monday and Wednesday at 7.30 P.M., by Mr. Hugh McKay, and in Dental Metallurgy on Tuesday and Thursday at 7, by Mr. W. Bruce Hepburn, L.D.S. Fee for each of the above courses of lectures, £3 3*s*. The lectures and instruction at the Glasgow Dental Hospital and School are recognised by all the licensing bodies in the United Kingdom. The fees for two years' hospital practice are £15 15*s*. Intending students before commencing to attend the lectures or hospital practice must produce evidence of having passed the preliminary examination prescribed by the regulations of the General Medical Council for registration of dental students. The hospital is opened daily from 5 to 7 P.M. (Saturdays excepted). Students may only enrol during the months of April or October. Summer session begins in April.

Glasgow Royal Infirmary (Dental Department).—Mr. Wm. Taylor attends at the Royal Infirmary at 3 P.M. on Mondays, Wednesdays, and Saturdays, and gives a course of instruction in Dental Surgery on these days in summer. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital. The winter session opens Thursday, Oct. 18th.

ANCILLARY SCIENTIFIC INSTITUTIONS.

ROYAL COLLEGE OF SCIENCE, London (with which is incorporated the **ROYAL SCHOOL OF MINES**).—Mechanics and Mathematics: Professor J. Perry, F.R.S., and Dr. A. R. Willis. Biology: Vacant (Zoology), and Professor J. B. Farmer, M.A., F.R.S. (Botany). Chemistry: Professor W. A. Tilden, F.R.S., and Dr. M. O. Forster, F.R.S. Physics: Professor H. L. Callendar, F.R.S., Dr. W. Watson, F.R.S., and Mr. A. Fowler. Geology: Professor W. W. Watts, F.R.S., and Dr. Cullis. Metallurgy: Professor W. Gowland. Mining: Professor S. H. Cox (temporary). The College reopens on Wednesday, Oct. 3rd, 1906. Communications should be addressed to the Registrar, Royal College of Science, South Kensington, S.W.

ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, Faraday House, 62–70, Southampton-row, W.C. —Principal, Hugh Erat Harrison, B.Sc. Lond. Instructor in Mathematics: Alexander Russell, M.A. Glasgow and Cambridge. Instructor in Chemistry: Mr. J. Thomas, B.Sc. Lond. Instructor in Mechanical Engineering: Mr. Walter H. Bell. This institution, in addition to its ordinary course of training in electrical engineering, which occupies two or three years, also arranges for special instruction in all branches of electricity either by private tuition or by a specially arranged course at the College or at the works of the companies with which it is associated. There are Entrance Scholarships of the value of 80 and 50 guineas, and Exhibitions of 40 guineas. Particulars may be obtained on application to the Secretary, Mr. Howard Foulds, Faraday House, Southampton-row, W.C. Session begins Sept. 17th.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Physics: Professor Arthur W. Crossley (Dean of the school). Botany: Professor Reynolds Green. Pharmaceutics: Professor Greenish. The session commences on Monday, Oct. 1st. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges. Application for admission to the school, or for further information, may be made to the Registrar, 17, Bloomsbury-square, London, W.C.

ROYAL SANITARY INSTITUTE (WITH WHICH IS INCORPORATED THE PARKES MUSEUM). PARKES MUSEUM, MARGARET-STREET, REGENT-STREET, W.—The objects of the Royal Sanitary Institute are to promote the advancement of sanitary science in all or any of its branches and to diffuse knowledge relating thereto. It was founded in 1876 and incorporated in 1888. Sessional meetings are held in London and in various provincial centres from time to time for the reading of papers and for discussions upon subjects connected with sanitary science, and lectures and demonstrations are arranged for sanitary officers in sanitary science as applied to buildings and public works. The lectures and demonstrations are suitable for foremen of works, builders, and those engaged in the allied trades; for army officers and professional men on food and meat inspection; for meat inspectors; and for school teachers. Examinations are held in London, provincial, and colonial centres and certificates of competency in sanitary knowledge are granted. The Parkes Museum, which is maintained by the institute, contains a great variety of the most approved forms of apparatus and appliances relating to health and domestic comfort. Professors and teaching of hygiene are allowed the use of the museum for demonstrations to their students on application to the committee. The museum is open daily from 9.30 A.M. to 5.30 P.M. and on Mondays to 8 P.M. and is free of charge except when lectures or meetings are being held. There are also a large library of sanitary literature which contains, in addition to standard works on sanitary science, a collection of reports of medical officers of health over the whole country, and a reading room supplied with the principal sanitary periodicals, both home and foreign. The institute is under the patronage of the King and the officers are: President, the Duke of Northumberland; chairman of council, Colonel J. Lane Notter, R.A.M.C.; treasurer, Mr. T. W. Cutler, F.R.I.B.A.; registrar, Mr. A. Wynter Blyth; and secretary, Mr. E. White Wallis. The lecturers are Dr. J. Priestley, Dr. G. Newman, Mr. A. Wellesley Harris, Dr. E. J. Steegmann, Dr. E. Petronell Manby, Professor H. R. Kenwood, Dr. P. Boobbyer, Dr. James Kerr, Colonel J. Lane Notter, R.A.M.C., Mr. J. Osborne Smith, Mr. W. C. Tyndale, M.Inst.C.E., Mr. A. Saxon Snell, F.R.I.B.A., Mr. J. E. Worth, M.Inst.C.E., Mr. J. Wright Clarke, Mr. W. Hunting, F.R.C.V.S., Mr. James King, M.R.C.V.S. For members the annual subscription is £2 2*s*. and for associates £1 1*s*., but members and associates holding certain qualifications only pay half the ordinary rate of subscription.

THE ROYAL INSTITUTE OF PUBLIC HEALTH.—The Royal Institute of Public Health, 37, Russell-square, W.C., was founded in the year 1886 with the object of obtaining the registration of public health diplomas and the further statutory requirement that all medical officers of health should possess such a qualification. In 1905 the Fellows and members of the Institute, now numbering nearly 2000, decided to create a central public health institution in London and have erected bacteriological, parasitological, and chemical laboratories in which researches of a public-health character are undertaken and the necessary training for obtaining such diplomas are provided, together with a library, lecture room, and common room. The Royal Institute of Public Health is recognised by the University of London as a public educational institution, and its course of instruction for the diploma by the universities and other examining bodies of the United Kingdom. The Institute is under the patronage of His Majesty the King, and the Right Hon. Lord Strathcona and Mount Royal is President. The teaching staff consists of—the Principal, Professor William R. Smith, F.R.S.E.; director of parasitological department, Dr. Louis W. Sambon; demonstrator of chemistry, Mr. C. E. Harris, Ph.D.; demonstrator of bacteriology, Dr. Carl Prausnitz. Occasional lectures are given by eminent sanitarians. The Harben lecturer for 1906 was Elie Metchnikoff of the Pasteur Institute, whose lectures were published in THE LANCET of June 21st.

Annotations.

"Ne quid nimis."

THE STUDY OF FRENCH AND GERMAN FOR MEDICAL STUDENTS.

IN THE LANCET of August 18th we published an annotation commenting upon the statement made by Mr. J. G. Robertson before the British Association that German had declined as a school subject in England in recent years. We urged our readers not to lose sight of the great value of a knowledge of German, and we have now received from Professor Osler the following memorandum which he issued to the Oxford undergraduates in medicine in November last relating to the importance of the study of French and German:—

"MEMORANDUM.

"During your undergraduate days you should become familiar with the French and German languages. To do this one of the best ways is to read small French and German text-books, of which (with the advice of colleagues) I inclose a list. Half an hour a day will soon give you the necessary facility in translation. Later in your course, get into the habit of reading, in the Radcliffe Library, a French and a German periodical. You will, in this way, become familiar with foreign literature, which has ever been deemed a necessary equipment of a cultivated physician.

List of French and German books recommended to undergraduates taking science courses preliminary to medicine, and to students of anatomy and physiology:—

French.

Aubert. Phénomènes de la Vie. 1*s.* 8*d.*
Ditte. Premières Notions de Chimie. 1*s.* 6*d.*
Joubert. Traité d'Électricité. 6*s.* 6*d.*
Meric. Dictionnaire des Termes de Médecine, Franç.-Anglais. 5*s.*

German.

Born (P.). Compendium der Anatomie des Menschen. Ein Repetitorium der Anatomie, Histologie und Entwicklungsgeschichte. Sewed, 5*s*; bound, 6*s.*
Reynolds. Leitfaden zur Einführung in die Experimentalchemie, 4 Vols.:—
  I. Einleitung. 1*s.* 6*d.*
  II. Metalloide. 2*s.*
  III. Metalle. 2*s.*
  IV. Chemie der Kohlenstoffverbindungen oder organ. Chemie. 2*s.* 9*d.*
Fiedler and Sandbach. A First German Course for Science Students. 2*s.* 6*d.*
Osbonne. German Grammar for Science Students. 2*s.* 6*d.*
Schenck und Gürber. Leitfaden der Physiologie des Menschen. 6*s.*
Lang and Abrahams. German-English Dictionary of Terms used in Medicine and the Allied Sciences. 15*s.*"

We are sure that it will profit as well as interest the readers of our Students' Number to have before them the list of French and German books which are recommended to the medical under-graduates of the University of Oxford by their learned Regius Professor.

THE STUDY OF MEDICAL HISTORY.

IT is a fact, significant in many ways, that Germany, *pari passu* with her exhaustive medical observation and research, devotes to the history of medicine a profound and comprehensive study which none of her contemporaries seem concerned to imitate. The British Isles, France, and Italy, notwithstanding their splendid, often epoch-making, contributions to medicine, scientific and clinical, have little or nothing to show in the investigation of its past as against the German work in that field. It must, we fear, be admitted that of the four literatures the British ranks lower than either the French or Italian in the history of medicine—having no counterpart to the Littré of the one or to the Puccinotti of the other, while all three are not for a moment to be compared to the German, as represented by Sprengel, Hecker, Haeser, Hirsch, and Virchow of a former generation and by Puschmann, Stieda, Ebstein, Neuburger, Magnus, Pagel, and Ribbert of that now passing. And yet there is no more interesting, we had almost said fascinating, field of study than the annals of the healing art, from its first rude beginnings so finely imagined by Lucretius in the prehistoric epoch down through all its revolutions to the present day when at last it has been recognised and cultivated as the veritable "nature-study" originally vindicated by Hippocrates. Most instructive, not seldom indeed humiliating, is it to realise how long it took the professional mind to get rid of "premature generalisation" begotten of the craving for "theoretical symmetry" and to school itself in the only method of interpreting and mastering nature, the method (in Bacon's words) of "serving and obeying" her. Again, to his surprise, if not to his self-complacency, the modern student will find that biological facts supposed to be of recent discovery were known to the Hellenic world. A beautiful demonstration of this has quite recently been made by Bloch, who has shown that Aristotle's views of embryology were in full anticipation of those now accepted, but that being overlaid and forgotten under the mediæval "Aristotelianism which was far removed from Aristotle," they had to wait till the nineteenth century before they were re-discovered. Fontana's finding of the nerve filaments in the eighteenth century was quite thrown away on his contemporaries; even the great Soemmering knew nothing of it; and once more the discovery had to be made anew in the nineteenth century by Treviranus. Authority, as well as non-recognition or imperfect appreciation, militated against scientific truth, and Harvey's magnificent discovery of the circulation had to flight its way to acceptance against prejudice reinforced by "officialdom." Most wisely indeed did Gagenbaur introduce his great and still popular text-book of human anatomy with a succinct narrative of the rise and progress of the science; and a service no less instructive and salutary to the clinical student would be rendered by a luminous, not necessarily long, statement of the "previous history" of diagnosis and treatment in the various groups of diseases. In malaria, for example, we are promised by Baccelli a study of its "etio-pathogenesis" (as he terms it), showing the conditions under which it made its appearance in such localities as the Roman Campagna—conditions traceable by a history going behind the mosquito which can "carry," but does not "cause," the disease. Here the question arises, How is the student to find time for the "History of Medicine" amid the many, well-nigh overwhelming, claims on his attention? The answer is that of the German schools. While a brief summary of its main facts may suffice in reference to the particular class-work in which the student may be engaged, let its study, comprehensive and systematic, form part of a post-graduate course when the young professional man has knowledge and experience enough to appreciate the steps and stages by which the present scientific standpoint has been reached. By that time his sense of proportion, developed and quickened, will enable him to estimate aright the pioneer labour, the spade-work, the tunnelling and bridge-making by which the provisional terminus at which he has alighted has been gradually led up to, itself in turn to become the point of a new departure on the ever-extending path towards the scientific ideal. Two admirable illustrations of what such a post-graduate course as that just indicated should convey have, opportunely enough, appeared during the twelvemonth now passing—to wit, the "Vorlesungen über Geschichte der Medizin," by Dr. Ernst Schwalbe of Heidelberg, and the "Grundriss eines Systems der Medizinischen Kulturgeschichte," by Dr. Julius Pagel, professor of medical history in the University of Berlin. These two by no means bulky volumes are well worthy of translation into English, not only as excellent manuals on their special subject, but as incentives to the English-speaking profession to coöperate in the cultivation of the same most interesting, most profitable, and, so far as its medical scholarship is concerned, too long neglected field.

A SPECIAL convocation of the University of Toronto was held last week in connexion with the meeting of the British Medical Association in that city at which the honorary degree of LL D. *honoris causâ* was conferred upon Professor Thomas Clifford Allbutt, M.D., F.R.S.; A. H. Freeland Barbour, M.D.; Sir Thomas Barlow, Bart., M.D.; Sir James Barr, M.D.; Sir William Broadbent, Bart., M.D.; George Cooper Franklin, F.R.C.S.; William Dobinson Halliburton, M.D., F.R.S.; Sir Victor Horsley, F.R.C.S., F.R.S.; Donald MacAlister, M.D.; William Julius Mickle, M.D.; and Dr. W. J. Mayo of Rochester, Minnesota; Dr. Louis Lapicque of Paris; and Dr. Ludwig Aschoff of Marburg. The same degree was also conferred *in absentiâ* upon Mr. H. W. Langley Browne, M.D., chairman of the British Medical Council. It is announced that the McGill University of Montreal will confer the same honour upon Professor Clifford Allbutt, Sir Thomas Barlow, Sir William Broadbent, and Sir Victor Horsley.

A COURSE of six lectures and demonstrations will be commenced at the Post-Graduate College and Polyclinic, 22, Chenies-street, Gower-street, London, W.C, on Monday, Sept. 10th, at 9 o'clock, by Mr. W. Stuart-Low.

POST-GRADUATE STUDY.

LONDON.

The London Post-Graduate Association.—The London Post-Graduate Association is now so well known that it is hardly necessary to remind our readers that it is composed of the following hospitals and medical schools (general and special)—viz.: *General Hospitals:* Charing Cross, Guy's, King's College, Middlesex, St. George's, St. Mary's, St. Thomas's, University College, and Westminster. *Special Hospitals:* The Brompton Hospital for Consumption and Diseases of the Chest, the Hospital for Sick Children (Great Ormond-street), the London School of Tropical Medicine, the National Hospital for the Paralysed and Epileptic (Queen-square), and the Royal London Ophthalmic Hospital (Moorfields). One ticket (the charge for which is 10 guineas for a three months' course, or 15 guineas for six months) admits the holder to the clinical instruction in the wards and out-patients' departments, the operations, necropsies, and other hospital practice of all the institutions mentioned above. The holder is also entitled to attend any special post-graduate classes which may be held from time to time at any of the general hospitals named. It is a result of the advances made in medical and surgical science during recent years that the practitioner who is unable to keep himself apace practically with these advances finds that he is after a time at a great disadvantage. For the purpose of enabling qualified medical men to keep up to date in their work we can heartily recommend the scheme offered by the London Post-Graduate Association, which thus places the best of all the hospital work in London at the disposal of its ticket-holders. The office of the association remains as before at the Examination Hall. Further particulars may be obtained by writing to the Secretary, the London Post-Graduate Association, Examination Hall, Victoria Embankment, London, W.C, or by personal application between the hours of 11.30 A.M. and 1 P.M., and 2 P.M. and 3 P.M. any week-day except Saturday.

Medical Graduates' College and Polyclinic.—This institution affords to medical practitioners special facilities for acquiring technical skill and for advancing their medical and scientific knowledge. The building contains lecture- and consulting-rooms, a pathological and clinical laboratory, a Roentgen-ray room, an ophthalmoscope room, a museum, a library, and reading- and writing-rooms, &c. Cliniques are given each working day of the week except Saturday at 4 P.M., and a lecture on medicine, surgery, or their special branches is delivered daily except Fridays and Saturdays at 5.15 P.M. Classes are also held in otology, laryngology, ophthalmology, radiography, anatomy, nervous diseases, microscopy, urinary analysis, gynæcology, practical bacteriology, mental diseases, hygiene and public health, and operative surgery. Extra classes in any subject are formed to suit the convenience of practitioners unable to attend those already provided. Special tutorial classes are held for practitioners reading for the higher examinations. A complimentary ticket available for three successive days will be issued to any practitioner upon presentation of his visiting card. A monthly journal, the *Polyclinic*, recording the work done in the college, is issued free to subscribers and members. The annual subscription for medical practitioners of either sex, holding qualifications granted in any British dominions, is one guinea. Full information can be obtained from the medical superintendent at the college, 22, Chenies-street, Gower-street, W.C. The autumn session commences on Monday, Sept. 10th.

Charing Cross Hospital.—Classes for post-graduate study are held on each Tuesday and Thursday of the week throughout the sessions of the medical school at Charing Cross Hospital. The fee for each complete course is £2 2*s.*, or for either day alone, £1 1*s.* The first of the two winter courses this year will commence on Oct. 4th. Short courses of instruction in special subjects (otology, laryngology, &c.) will be arranged if a sufficient number of gentlemen give in their names as wishing to attend. Further information as to the dates and subjects can be obtained by communicating with the honorary secretary (Dr. Bosanquet) at the hospital.

In connexion with the hospitals of the Seamen's Society there are two post-graduate schools—viz., (*a*) the London School of Tropical Medicine; and (*b*) the London School of Clinical Medicine.

(*a*) *The London School of Tropical Medicine.*—The school buildings, laboratories, museum, library, &c., are within the grounds of the Branch Hospital, Royal Victoria and Albert Dock (station Connaught-road, Great Eastern Railway). Opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates before entering the service or going abroad. In the hospitals of the society are to be found cases of tropical diseases such as may be met with in actual practice in the tropics. There are three courses in the year, each lasting three months, beginning Oct. 1st, Jan. 15th, and May 1st respectively. The laboratory, museum, library, &c., are open daily and clinical instruction is given daily in the wards of the hospitals. The lecturers in the school are: Sir P. Manson, F.R.S., Dr. Andrew Duncan, Dr. L. Westenra Sambon, Dr. J. M. H. Macleod, Professor R. Tanner Hewlett, Mr. James Cantlie, Mr. E. Treacher Collins, Dr. A. Crombie, Dr. F. M. Sandwith, Mr. Goodby, and Professor W. J. Simpson. The medical superintendent is Dr. C. W. Daniels. Certificates are granted after examination to those who complete a full course. Resident chambers are available for students, who must be qualified or in the fifth year of their medical studies. Prize: the Craggs prize of £50 is awarded yearly.

(*b*) *The London School of Clinical Medicine* (for qualified practitioners only).—The lecture rooms, pathological laboratories (two), museum, and operative surgery class-rooms, are in the *Dreadnought* Hospital at Greenwich, and the whole hospital of 250 beds with its Out-Patient Departments is open to students from 10 A.M. till 5 P.M. Medical, Surgical, and Special Department In-patient Cliniques are held upon every afternoon except Saturday by the senior members of the staff and operations are performed daily, whilst out-patients in the Medical, Surgical, and Special Departments are demonstrated by the assistant physicians and assistant surgeons daily in the forenoon. Practical classes are arranged three times a year in the following subjects: The Practice of Medicine; the Practice of Surgery; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Diseases of the Nervous System; Operative Surgery; Clinical Pathology, Microscopy, and Bacteriology; Mental Diseases; Radiography; Dental Surgery; the Administration of Anæsthetics; Hygiene and Public Health; Gynæcology; Surgical Diseases of Women; Surgical Diseases of Children; Medical Diseases of Women; Medical Diseases of Children; Applied Anatomy; and Midwifery.

Three sessions of ten weeks' duration are held in each year, beginning on Jan. 15th, May 1st, and October 1st. Every variety of disease may be studied in the wards and out-patient rooms of the hospital, at the dispensaries, and at the affiliated hospitals. Male patients only are received as in-patients by the Seamen's Society but arrangements have been entered into with the Royal Waterloo Hospital for the reception of graduates who desire instruction in diseases of women and children; with the Bethlem Hospital for those who require tuition in mental disease; and with the General Lying-in Hospital, York-road, for the prosecution of study in midwifery. These hospitals are situated on the south side of the river, are directly linked to the *Dreadnought* by both railway and tramway, and are affiliated to the London School of Clinical Medicine. The certificates of the School are recognised by the Admiralty, the War Office, and the University of London (for the higher degrees). The supply of material affords exceptional facilities for practical instruction in operative surgery and in pathology on the cadaver. The hospital also offers a wide field for the study of venereal diseases and there is a special department with open-air wards for the treatment of tuberculosis. The teaching staff is: Sir Dyce Duckworth, Dr. Frederick Taylor, Dr. J. Rose Bradford, F.R.S., Dr. R. Tanner Hewlett, Dr. Guthrie Rankin, Sir William H. Bennett, K.C.V.O., Mr. A. W. Mayo Robson, Mr. Albert Carless, Mr. William Turner, Mr. Lawrie H. McGavin, Mr. L. Vernon Cargill, Mr. Malcolm Morris, Dr. StClair Thomson, Dr. James Mackenzie Davidson, Dr. S. Russell Wells, Dr. A. Ernest Jones, Mr. Harold Burrows, Mr. E. Rock Carling, Mr. Stephen Mayou, Dr. Wilfrid Fox, Mr. A. Lawrence, Dr. Maynard Horne, Dr. Cecil Hughes, Dr. Vivian B. Orr, Mr. T. Graham Scott, Mr. W. Kenneth Steele. The extra-mural lecturers are: Dr. James Taylor, Dr. W. H. B. Stoddart, Dr. W. J. R. Simpson, Dr. James Cantlie, Dr. William J. Gow, Dr. Herbert Williamson, Mr. Russell Howard, Mr. Herbert S. Pendlebury, Dr. Alexander Haig, Dr. Robert O. Moon, Dr. Charles O. Hawthorne, Dr. Thomas D. Lister, Dr. William Radford Dakin, Dr. Robert Boxall, and Mr. W. Johnson Smith.

The prospectuses, syllabuses, and other particulars of both schools can be obtained on application to the Secretary, Seamen's Hospital, Greenwich, S.E., or from the Medical Superintendents at the Schools.

West London Post-Graduate College, West London Hospital.—The West London Post-Graduate College was started in 1895 and three years later its basis was enlarged by the provision for the post-graduates of lecture-, reading-, and waiting-rooms, &c., while owing to the continued growth of the college these were transferred in 1901 to a building especially constructed for the purpose. Over 1100 post-graduates have been enrolled since its establishment, the yearly entry being now about 200. The hospital, which contains 159 beds, is in the main Hammersmith road, about three miles from Hyde Park Corner, and very accessible by omnibus, tram, or train. The physicians and surgeons attend daily at 2.30 P.M. Post-graduates accompany the staff and the junior staff on their visits to the wards. Instruction is given in the out-patient department daily at 2.15 P.M. by the assistant physicians and assistant surgeons. The out-patient department has recently been enlarged and there is now ample accommodation for post-graduates to see and examine the patients in all the special departments of the hospital. Clinical assistants for special work are appointed from among the post-graduates, and practical classes, limited in number, for instruction in these subjects, as well as in medicine and surgery generally, are held as required. Operations are performed daily at 2.30 P.M. Post-graduates are allowed to stand close to the table and can see the operations perfectly. The surgeons often avail themselves of the assistance of post-graduates at operations. Instruction is given in the administration of anæsthetics by the anæsthetists on the operating days and post-graduates are allowed to administer anæsthetics under their superintendence. Post-mortem examinations are performed at 12 noon or 1.30 P.M., and demonstrations on recent pathological specimens are given on Mondays at 12 noon during each session in the pathological laboratory. Practical lectures and demonstrations are given each afternoon (except Saturdays), at 5 P.M., during the session. Included in this course are lectures by outside specialists on mental diseases and on public health, and in connexion with the former instruction is also given in certain asylums. The college is licensed for the teaching of operative surgery. The fee is £4 4s. each member in a class of four. The practice of the hospital is well adapted to the needs of medical officers of the Royal Navy and officers of the Royal Army Medical Corps who have obtained leave for further professional study, and the certificate of attendance at the college during such leave is recognised by the Admiralty. The pathological laboratory has just recently been completely reorganised and placed in the hands of the pathologist, Dr. G. C. Low, who attends there during the whole day. Post-graduates are given instruction in bacteriology and microscopy and Tropical Medicine. A special class meets on three mornings a week from 11 to 1, and post-graduates joining the class can work in the laboratory at other times under the guidance of the pathologist. A class will consist of 12 meetings and will commence at the beginning of each month. The fee for this class in bacteriology and microscopy will be £3 3s. The fee for the hospital practice, including all ordinary demonstrations and lectures, is £1 1s. for one week, £3 2s. for one month, £5 5s. for three months, £8 8s. for six months, £12 12s. for one year, and £25 for a life ticket; all fees to be paid in advance. A practitioner who cannot attend the whole course may attend any ten lectures or demonstrations during the session for a fee of £1 1s. A vacation class is held each year in August, the fee being £2 2s. for the course of one month, including hospital practice, or a ticket for a fortnight's hospital practice, including the lectures, can be obtained for £1 11s. 6d. The fee for a three months' course of instruction in the administration of anæsthetics, including a special class, is £3 3s., or without the class, £2 2s. A ticket for any of the above courses will be issued at any date. Arrangements can be made for gentlemen working for higher university examinations to be coached. The Winter Session commences on Monday, Oct. 8th. All communications to be addressed to the Dean, Mr. L. A. Bidwell, Post-Graduate College, West London Hospital, Hammersmith, W.

West-End Hospital for Diseases of the Nervous System.—A course of post-graduate lectures on diseases of the nervous system will be given at this hospital on Thursdays, at 5 P.M., as follows.—Nov. 1st: Dr. Harry Campbell, Demonstration of Cases. Nov. 8th: Dr. T. D. Savill, Hysterical Disorders and their Treatment. Nov. 15th: Mr. Laming Evans, Surgical Treatment of Contractures of the Hip due to Nervous Disorders. Nov. 22nd: Dr. F. S. Palmer, Friedreich's Disease. Nov. 29th: Dr. Dundas Grant, Nervous Disturbance in Connexion with Aural Disease. Dec. 6th: Dr. E. Macnamara, Tics. Members of the medical profession are admitted on presentation of their cards.

North-East London Post-Graduate College.—This post-graduate school is established in connexion with the Tottenham Hospital, N. (see p. 574), which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees. Facilities are there afforded to qualified medical practitioners for taking part in the work of an active general hospital of 120 beds and for attending demonstrations of various branches of medicine, surgery, and gynæcology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers, psychological medicine, the administration of anæsthetics, and dentistry. Cliniques, lectures, and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week except Saturday. Special classes, the attendance at which will be limited, are arranged in gynæcology, the surgical diseases of children, including orthopædic surgery, diseases of the throat, nose and ear, diagnosis of diseases of the chest, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, analysis of gastric contents, clinical examination of the blood, diseases of the skin, abdominal surgery, radiography, bacteriology, and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month two guineas), and a perpetual ticket for the practice of the hospital may for the present be obtained on payment of a fee of five guineas. Medical practitioners who have attended a three months' course in any departments are eligible for appointment as clinical assistants in those departments. A certificate, signed by the staff, may be obtained at the end of three months' hospital attendance. A pathological museum and a pathological laboratory are available. A reading- and writing-room, containing a reference and lending library, is provided, and tea may be obtained. The hospital is connected with the Telephone Exchange (No. 23, Tottenham).

The opening lecture of the winter session, in conjunction with that of the North-East London Clinical Society, will be given at the hospital at 4 P.M. on Oct. 18th by Sir Halliday Croom.

The lecturers are as follows:—In General Medicine: Dr. Percy Kidd, Dr. R. Murray Leslie, Dr. G. P. Chappel, Dr. A. J. Whiting, and Dr. D. Forsyth. In General Surgery: Mr. John Langton, Mr. Walter Edmunds, and Mr. H. W. Carson. In Gynæcology and Obstetrics: Dr. Arthur Giles. In Diseases of the Eye: Mr. R. Philip Brooks. In Diseases of the Ear, Throat, and Nose: Mr. H. W. Carson. In Diseases of the Skin: Dr. G. Norman Meachen. In Fevers (at the North-Eastern Fever Hospital, St. Anne's-road): Dr. H. E. Cuff. In Diseases of Children: Dr. G. F. Still. In Psychological Medicine: Dr. H. Corner. In Diseases of the Chest (at the Mount Vernon Hospital and the Northwood Sanatorium): Dr. J. E. Squire. In Tropical Medicine: Mr. James Cantlie. In Radiography and Medical Electricity: Mr. Higham Cooper. In the Administration of Anæsthetics: Mr A. de Prenderville. In Pathology and Bacteriology: Dr. Basil Price.

Further information, with prospectus and syllabus of lectures and demonstrations, may be obtained from the Dean of the School, Dr. A. J. Whiting, 142, Harley-street, London, W.

PROVINCIAL.

Birmingham.—At the University of Birmingham special courses for post-graduates have not yet been instituted, except in the subject of Advanced Bacteriology (January to March) and Clinical Pathology and Bacteriology (April to June), but the various departments of the University are open to graduates who can attend any of the systematic courses on payment of a fee. Graduates may also work in the laboratories under the supervision of the professors for a small fee to cover the incidental expenses. Applications for information should be made to the Dean.

Bristol.—Courses of post-graduate instruction adapted to the requirements of those proceeding to the M.D. degree of the Universities, each lasting about 12 weeks, will be held at the Bristol Royal Infirmary and General Hospital. The course will consist of: (*a*) clinical demonstrations on cases selected from the wards and from out-patients in medicine, obstetrics, dermatology, and laryngology; and (*b*) tutorial classes in medicine, obstetrics, pathology, laryngology, bacteriology, and dermatology. Classes in clinical medicine will be held twice a week—once at the Infirmary and once at the Hospital—by Dr. J. E. Shaw and Dr. F. H. Edgeworth at the Infirmary and by Dr. J. Michell Clarke and Dr. J. O. Symes at the Hospital. Classes in obstetrics will be held once a week on alternate weeks at the Infirmary and Hospital by Dr. Walter C. Swayne and Mr. D. C. Rayner respectively. A class in pathology will be taken once a week in the museums of the Infirmary and Hospital on alternate weeks by Professor Walker Hall and Dr. Newman Neild respectively. Six demonstrations on dermatology will be given by Dr. J. A. Nixon and Dr. W. K. Wills at the Infirmary and Hospital. Six demonstrations on laryngology will be given by Dr. Watson Williams at the Infirmary. A practical course in bacteriology consisting of six demonstrations will be held by Professor Stanley Kent at University College. A tutorial class in medicine will be held on one evening a week by Dr. G. Parker, Dr. Newman Neild, and Dr. J. R. Charles in rotation and a similar class in obstetrics will be taken once a week by Dr. Walter Swayne and Mr. Rayner alternately. The fees are as follows:—For the whole course, £7 7*s.*; for classes in clinical medicine, pathology, laryngology, and bacteriology and tutorial class in medicine, £5 5*s.*; for classes in obstetrics, pathology, and bacteriology, £3 3*s.*; and for clinical medicine and obstetrics only, £3 3*s.* Applications to attend the classes should be made to Dr. Walter Swayne, 56, St. Paul's-road, Clifton, Bristol.

Cambridge.—Long vacation courses are held at Cambridge during the month of July. This year the course included lectures and demonstrations on general and special pathology by Professor G. Sims Woodhead, Dr. W. Malden, and Dr. G. S. Graham Smith on phagocytosis, "opsonins," toxins and antitoxins, methods of standardisation, the iodophil reaction in blood, diphtheria, agglutinins and agglutination methods, precipitins, and hæmolysins. If a large enough number of names are sent in a course in pharmacology (Dr. W. E. Dixon) and a series of lectures and demonstrations on protozoal diseases (Dr. G. H. F. Nuttall) can also be arranged. The pathological and pharmacological laboratories are open to advanced students and graduates. Applications for information should be made early in the year to Professor Sims Woodhead.

Liverpool.—At the University of Liverpool the department of Bio-chemistry is devoted entirely to post-graduate teaching and research upon chemistry in relationship to biology and medicine. The laboratory is open daily for research, and courses of laboratory instruction in those parts of the subject most closely related to medical work are given for medical practitioners by arrangement with Professor B. Moore. A course of lectures and demonstrations in comparative bacteriology and parasitology is given during the autumn and Lent terms by Dr. H. E. Annett, who also conducts a course of lectures and demonstrations in comparative pathology during the summer term. By special arrangement a practical course in clinical bacteriology and hæmatology is given twice weekly during the summer term by Dr. W. B. Warrington and Dr. E. E. Glynn. The Thompson Yates and the Johnston laboratories are open for post-graduate research in pathology and physiology during the winter and summer sessions under the supervision of Professor Rubert Boyce and Professor C. S. Sherrington. Courses on special subjects are given by other lecturers of the University during the summer session by arrangement with medical practitioners. At the Liverpool Royal Infirmary special arrangements exist whereby medical practitioners can keep in touch with the most recent methods adopted in hospital practice.

Manchester.—The plan adopted a few years ago of having special courses of lectures on medicine and surgery for qualified medical men has since that time been considerably modified. Classes are now held and lectures given on various special subjects, as, e.g., diseases of the heart, diseases of the respiratory organs, of the kidney, and so on, and the same obtains as to surgical matters. These lectures are designed to meet the wants of senior students and practitioners. The public health department, presided over by Professor Delépine, is largely attended by medical men, as are also the lectures on bacteriology given in the College course by Dr. Sidebotham. There is no difficulty in Manchester in the way of any practitioner who wants to have his recollections revived or his knowledge enlarged and brought up to the present standard in accomplishing his wish.

Sheffield.—At the University of Sheffield post-graduate courses are held in bacteriology and applied anatomy. Occasional courses are also given in operative surgery and clinical surgery.

Newcastle-upon-Tyne.—At the University of Durham courses of instruction are given in chemical and physical laboratory work and lectures are delivered on comparative pathology and practical bacteriology for the diploma in public health and the degree of bachelor in hygiene.

SCOTLAND.

Aberdeen.—Although there is no special provision at Aberdeen for post-graduate study such as exists in London, still there are some facilities for doing work of this nature at the University. There are fully equipped laboratories in anatomy, anthropometry, bacteriology, botany, chemistry, pharmacology, physics, physiology, public health and zoology. Graduates or others desiring to engage in special study or research may be admitted by the Senatus to prosecute such study or research in any of the laboratories in accordance with certain provisions. Research students are exempted from payment of laboratory fees but are required to matriculate each year, paying the ordinary matriculation fee (£1 1*s.* for winter and summer; 10*s.* 6*d.* for summer). Forms of application for admission as research students may be had from the secretary of the Senatus. The fees are £3 3*s.* for six hours per week in winter or nine hours per week in summer, 10*s.* 6*d.* and 7*s.* being charged for every extra hour per week in winter and summer respectively. The fee for the Public Health Laboratory for six months is £6 6*s.*, and for the bacteriological laboratory for three months is £4 4*s.*, £3 3*s.*, and £1 11*s.* 6*d.* being respectively charged for a half course or any less time. At the Royal Lunatic Asylum, accommodating above 700 patients (fees, £2 2*s.* for three months), arrangements are made for extra teaching in the higher departments of medical psychology and cerebral pathology for graduates who desire it or wish to obtain the certificate of the Medico-Psychological Association of Great Britain and Ireland

Clinical work may be done at the following places:—(General Hospital): Aberdeen Royal Infirmary (accommodating 200 patients, perpetual ticket £6, or *first* year £3 10*s.* and second year £3, thereafter free); Sick Children's Hospital (75 patients; first year £2 2*s.*, then £1 1*s.*); City (Fever) Hospital (100 beds; £1 1*s.* for three months); General Dispensary and Lying-in and Vaccine Institution (10,000 out-patients per annum; perpetual fee £3 3*s.*); and Ophthalmic Institution (16,000 patients per annum, fee £1 1*s.*). During the summer session (April to June) special classes, each costing £2 2*s.*, are held at the Royal Infirmary, the subjects being Diseases of the Skin, Medical Electricity, Dental Surgery, Anæsthetics, Ophthalmology, and Gynæcology. Lectures on Diseases of the Ear and Throat are given at the dispensary and on Tropical Medicine at Marischal College. In Tropical Medicine the course embraces attendance on (1) the ordinary course of Bacteriology (Systematic and Practical) as required for M.B., Ch.B., or D.P.H.; and (2) special course of 25 lectures on Tropical Medicine. A detailed account is given of malarial fevers, including hæmoglobinuric fever, yellow fever, plague, dengue, Malta fever, heat stroke, and other fevers found in the tropics, beri-beri, cholera, dysentery, sprue, tropical liver diseases, leprosy, yaws, oriental sore, filariasis and parasites generally, and mycetoma.

Edinburgh.—A post-graduate vacation course in medicine, in connexion with the University and Royal Colleges, has been instituted, and will be held during the present year from Sept. 17th to Oct. 6th. The course will consist of lectures, demonstrations, and practical hospital and laboratory work in the various departments of medicine and surgery and full advantage will be taken of the opportunities for clinical work offered by the Royal Infirmary, Royal Hospital for Sick Children, and the Royal Maternity Hospital. Instruction may be obtained throughout the year as heretofore, but particularly during the summer session, in a number of subjects in special courses provided by members of the extra-mural school for graduates and senior students. Since the introduction of an examination for the degree of Doctor of Medicine these classes have been taken advantage of by those proposing to go on to this examination. During the weeks preceding the examination there are short special courses in ophthalmoscopy, in laryngology, in clinical pathology, in the examination of the blood, in bacteriology, and in the methods of physical diagnosis. The classes are mainly practical and are much valued by graduates as a means of brushing up their knowledge.

Glasgow.—At Glasgow the possibilities for post-graduate work are considerable and in almost every department graduates have opportunities for acquiring more special knowledge or carrying on original work. In pathology, courses in "Practical Bacteriology" and "Pathological Histology" for graduates will be commenced in the pathological department of the Western Infirmary on Monday, Oct. 22nd. The courses will extend over eight weeks, each class meeting thrice weekly. The fee for either course is £3 3*s.*, and for both courses £5 5*s.* In the Pathological Institute there is a limited number of rooms specially fitted up for research work and arrangements can be made for graduates who are desirous of engaging in work of this nature. Those interested in embryology may take out the practical course, or if they desire to do special work may obtain the use of a table in the embryology laboratory with such guidance and help as the lecturer can give. The University also has the right of nomination to a table in the laboratory of the Marine Biological Station at Millport. This station is very well off as regards the richness and variety of the fauna which can readily be obtained and kept alive in the tank rooms under approximately natural conditions. It thus offers facilities for various kinds of biological study and particularly for physiological and pharmacological work on the marine invertebrates. In public health the University now gives the degrees of B.Sc. and D.Sc. according to the conditions laid down in the ordinances. Post-graduate instruction in public health laboratory work is given in the University laboratory during both winter and summer sessions, and opportunities are offered under prescribed conditions for original research work. In physiology and materia medica such facilities as are possible are afforded to those wishing to engage in original research work. A course of lectures on Physiological Chemistry will be delivered in the winter months by Dr. E. P. Cathcart, University lecturer on Physiological Chemistry. It may be noted that new laboratories for physiology, materia medica, and public health are now in the course of erection. So far as can be ascertained it is not likely that the building and equipment of the new premises will be completed before the spring of 1907, but when completed these laboratories will be provided with rooms suitably equipped for research work, in which graduates will be able to work in absolute privacy except in so far as they may wish advice and assistance from the teaching staff. A course of clinical surgery or clinical medicine may be taken at the Western Infirmary on payment of a fee of £2 2*s.* to the hospital and £3 3*s.* for clinical instruction. At the Eye Infirmary during the early winter months a post-graduate course of about a dozen lectures and demonstrations on Diseases of the Eye will be conducted by the surgeons of the infirmary. No charge is made for this course. Dr. Freeland Fergus at the Western Medical School lectures to graduates from November to February on Diseases of the Eye. The fee for this course is £1 1*s.* At the Maternity Hospital courses in midwifery commence every month. The fee for the first month is £2 2*s.* and later is £1 1*s.* per month. Those taking out this course see all the work of the hospital and are allowed to undertake obstetric cases and minor operations, both in the internal and external work of the hospital. The opportunities thus afforded are exceptional when we consider that each year on an average 20 Cæsarean sections are performed and forceps are used in 250 cases. At Anderson's College Medical School a six months' course of laboratory instruction in public health is given which is recognised by the Scottish colleges and by the University of Cambridge as qualifying for their Diplomas in Public Health. Supplementary to the laboratory work a three months' course of lectures is given when required on "Physics, Meteorology, Practical Sanitation, Sanitary Law, and Vital Statistics." By attendance on this course candidates for D.P.H. are exempted from three months of the necessary six months' out-door work. Graduates desirous of taking out a course of operative surgery can obtain the necessary facilities by arrangement with the Dean of Anderson's College. A new course at the Royal Infirmary will be opened on Sept. 4th by Major George Lamb, M.D., I.M.S., by a lecture on the Etiology of Plague. In organising these courses the endeavour has been to make them as practical as possible and to devote attention especially to diagnosis and the newer methods of investigating disease. The practically unlimited material at the Royal Infirmary affords facilities for studying disease in all its phases and enables the teachers to demonstrate a great variety of cases illustrating details in diagnosis which in a smaller clinical field would be impossible. The courses are arranged differently from time to time so as to give a variety in the grouping of subjects and a rotation in the teachers. The course to be opened on Sept. 4th will include 120 meetings. The series are:—1. Diseases of the Eye: Dr. A. Maitland Ramsay. 2. Diseases of the Kidney and Bladder: Dr. David Newman. 3. Clinical Medicine: Dr. J. Lindsay Steven and Dr. T. K. Monro. 4. Clinical Surgery: Mr. John Barlow, Mr. H. Rutherfurd, and Dr. A. N. McGregor. 5. Diseases of the Ear: Dr. J. Kerr Love. 6. Diseases of the Throat and Nose: Dr. Robert Fullerton. 7. Hæmatology: Dr. W. K. Hunter. 8. Gynæcology: Dr. Balfour Marshall. 9. Practical Pathology: Dr. Charles Workman. 10. Bacteriology: Mr. David McCrorie. A copy of the syllabus may be had by making application to Dr. Maxtone Thom, superintendent of the Royal Infirmary.

IRELAND.

Belfast.—At Queen's College a course in clinical pathology, consisting chiefly of practical instruction, is given during the summer session, and, should a sufficient number desire to attend, a post-graduate course of practical work in the application of methods of chemical physiology to clinical investigation is also held. A course in clinical pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in this department for the public health committee of the Belfast corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, and the diagnosis of cases of infectious diseases. Subject to the number of students presenting themselves, arrangements are made for the necessary practical instruction (1) in the chemical laboratories; (2) in the pathological and bacteriological laboratories; and (3) for outdoor sanitary work under the medical officer of Health of Belfast. These courses have been approved by the Privy Council in connexion with the degree of M.D. in State Medicine in the University of London. The certificates of these courses are also accepted for the diploma in public health granted by the

Royal University of Ireland, the University of Cambridge, and the various licensing bodies.

Dublin.—At Trinity College, during the summer session, a three weeks' post-graduate course is given. This includes instruction in pathology, clinical medicine, and surgery; diseases of the ear, throat, and nose; diseases of the eye; gynæcology; anatomy; x rays; operative surgery (on the cadaver); diseases of the skin and cystoscopy. The various lectures and practical courses are given in the laboratories of Trinity College and the clinical instruction is given at certain of the Dublin hospitals. The fee for the course is £5 5*s.* and arrangements are made enabling a limited number of the class to live in college rooms and dine in hall at a cost of £1 per week. Full particulars and a time-table of the classes may be obtained from the Honorary Secretary, Dr. Alfred R. Parsons, Lower Fitzwilliam-street, Dublin.

At the Royal College of Surgeons in Ireland post-graduate courses will be held from Sept. 24th to Oct. 13th. Courses are also held at the end of the summer session. Further particulars can be obtained from Professor Fraser at the Royal College of Surgeons.

Arrangements are also concluded by the Medical Board of the Mater Misericordiæ Hospital for the delivery during each summer of a full course of post-graduate instruction in connexion with the Medical School of the Catholic University.

THE BRITISH MEDICAL MAN ABROAD.

THE conditions of medical practice have much altered in this country of late. Professional incomes in many places have been lowered seriously by the unfair tactics of so-called medical aid societies, and the position of servant to which some of these associations would reduce their medical officer is one that liberally educated gentlemen do not welcome with enthusiasm. We have pointed this out with much detail in many issues of THE LANCET and we have reason to think that improvement is at hand, but there is yet a time of severe struggle ahead. Again the expenses of living have gone up for medical men as they have for all the middle and upper middle classes of the country, while more money is required to secure the necessary medical degrees and diplomas owing to the longer curriculum and the more expensive equipment. These facts account, though only partially, for the increased number of medical men who having obtained British medical qualifications desire to settle abroad. Other factors at work are the spirit of adventure, the feeling that in a new country there is more elbow-room and more chances of getting out of the ruck, and the increased facilities of transport. Newspapers and books galore nowadays make us familiar with life in other lands, while trains and steamers will take us all over the world in a short time and at a comparatively small expense. For this reason or that, the number of medical men who make inquiry from us as to their legal and professional position in a foreign country grows yearly larger, and in the following columns we make an attempt to give the information that is usually sought.

Speaking generally, our colonies make it easy for medical men from home to practise there, but the same is not the case on the continent, where there is an obvious tendency towards protection. But in the colonies there are not many openings for practice except for those who are willing to "rough" it and work hard. In Canada there are outlying districts of British Columbia where a good start might, perhaps, be obtained; but it must be remembered that Canada possesses advanced medical schools and is a sparsely populated country as yet. In Australia the prospect for the British practitioner is not greater than that which faces him in Great Britain. The medical profession is, in fact, crowded in all places at home and abroad where the circumstances of practice are favourable, and many practitioners who have gone out from the mother country have had to leave the colonies unsuccessful, or have been very hard pushed to make both ends meet. The graduates of the colonial universities every year more than meet the usual vacancies, and the local men as a rule get on better than strangers, having friends to talk of them and help them to official positions. It used to be generally believed that, even where there was a large supply of general practitioners in the big colonial towns, there would still be good openings for men who have specialised in such branches of practice as the treatment of eye and ear diseases. This is partially true. There are openings of which good men can take advantage. But as a rule the openings in the colonies for new comers are in country districts where the medical man, besides being proficient in every branch of the profession, must be ready to lead a hard life. It is desirable that every colonial practitioner, intending to start in a country district, should be of good physique and not only able to ride but able to take care of his horses.

There are, of course, certain colonial appointments made in this country particulars of which will be found in our columns.[1] In various districts of South Africa there are appointments as district surgeons and railway surgeons made by the Colonial Office. Candidates for these posts should apply to the assistant private secretary at the Colonial Office for information, and their chances of success will be much increased by having passed through one of the schools of tropical medicine. The duties of colonial medical officers involve medical charge of a district, including as a rule the charge of a hospital and a lunatic asylum. The medical officers also supervise the sanitation of their districts, and as a rule give gratuitous attendance to all Government officials.

The United States of America form a rich and well-populated country to which, as speaking our language, it is natural for the British medical man to desire to go. The regulations for practice in the various States differ much, but it will be found that wherever the social conditions are pleasant and the opportunities for emoluments good there will be plenty of competition. There is an enormous number of medical men in the United States, the proportion of population to medical men in some of the thickly populated centres being not more than 500 to 1. The British medical man contemplating starting in medical practice in the United States will be prudent to make full inquiry before deciding on the locality, and his chance of success will be enormously increased by his having some good introductions.

FRANCE.

No one—native or foreign—can practise on French territory unless he be provided with the degree of M.D. of a French faculty. Five examinations have to be passed and in addition a thesis must be written and "sustained" (*defended*). In the class attendance and in the professional examinations no allowance or concession is made to *foreigners* in respect of any medical classes which they may have attended or any qualifications which they may have obtained in any other country. Foreigners who intend to practise on French territory must before commencing their medical studies take the certificate in general education known as the "*diplôme de Bachelier de l'Université.*" Foreigners may graduate as M.D. at a French university without this "diplôme," but in that case they cannot practise in France. The majority of the graduates of this class are Roumanians, Servians, and residents in South America.

As regards the time necessary for the passing of these examinations qualifying for the M.D. degree, the 16 "inscriptions" are given *en bloc* to a qualified foreigner, who may consequently pass his examinations as rapidly as is convenient to himself. Nearly all the examinations are *vivâ-voce* in French only. A British practitioner desirous of qualifying in France must address an application to that effect to the Minister of Public Instruction, and at the same time forward to that Minister a translation into French (by a sworn translator—*traducteur juré*) of his certificate of birth and diplomas duly viséd by the British consul. Provided the British practitioner in France be not obtrusively combative and insular in his ideas his social position depends entirely on his scientific merits, and may be a very good one.

ITALY.

Some years ago the British and American consuls at the great centres of Italian population and commerce combined to form an estimate of the money brought annually into the kingdom and spent within its borders by the English-speaking world. That estimate, an approximate one necessarily, which they carefully checked by every qualifying consideration conceivable, amounted to £20,000,000 sterling, about one third of Italy's whole revenue at that time. Since then the yearly influx of English and especially of American visitors has greatly increased, so that were a similar calculation to be made now the estimate would doubtless be still larger. This is a fact of great importance from whatever side it is contemplated. For us, as medical journalists, representing the interests of the profession, it has peculiar significance, first, as implying a necessarily large and continuous demand for English-speaking practitioners; next, as also implying on the part of Italy a sincere wish in her own self-interest to welcome such practitioners. It is true that of late years an active agitation, having for its object the expulsion of all foreign practitioners from the country, has been carried on by a section of the medical profession in Italy, but the movement has proved only partly successful, the public at large being well aware of the injury which the adoption of such a measure would inflict upon its interests. The British medical men and their American *confrères* form a prominent reason for Italy continually to attract that portion of the travelling public from which she derives so much of her annual revenue. There are therefore excellent reasons why every facility should be offered to them for exercising their calling freely in her cities and health resorts, and we may state at once that the regulations which still exist in Italy with respect to the foreign practitioner are most liberal and fair, it being open to anyone possessing a medical qualification recognised as legal in the country of its origin to engage in practice amongst the foreign visitors and residents within her borders. The restrictions ruling in Switzerland, France, and, indeed, nearly every other European country, do not exist in the Italian kingdom. The medical man's qualification, certified by ability to produce his diploma, is quite sufficient. He has, therefore, (*a*) no examination to pass; (*b*) no fees to pay; (*c*) no Government forms to comply with; and (*d*) requires no previous residence in the country as a "condition precedent" to practise. On the other hand, in a country compelled by its financial requirements to impose taxes in every possible direction the English-speaking practitioner has to pay the heavy income-tax ("ricchezza mobile" it is called) of nearly 13½ per cent., besides being liable to the comparatively mild "tassa di famiglia" (tax on domestic servants, &c.), levied on foreign and native residents alike. As to the career Italy offers to the English-speaking practitioner it is in some respects better, in other respects worse, than it was some years ago. It is better inasmuch as Italian medicine and surgery have greatly improved of late years and the foreign practitioner, particularly in those cities which are the seat of medical schools, is not in danger, as he used to be, of getting out of touch with the advance of the profession. Indeed, the British medical man may keep himself *au courant* with the latest accession to medical doctrine as conveniently in the Italian as in any other kingdom. By graduating at one or other of the many Italian schools he can obtain the *entrée* to the medical societies, the congresses (provincial and national), the hospitals, the class-rooms open to the native practitioners, and also become entitled to the reduced railway and steamboat fares conceded on occasion to all duly qualified Italians. Indeed, he is generally welcome to them on the ground of professional *fratellanza* (brotherhood), but the graduation above indicated gives him a right to what he would otherwise owe merely to courtesy. On the other hand, the career is less favourable than formerly on account of the larger number of English-speaking competitors whom it now attracts and who comprise not only Englishmen and Americans, but Swiss, Germans, and other nationalities as well. Their harvest (generally limited to three or four months of the "season") entails immense, almost excessive, activity, compensating the comparative idleness of the months before and after it. Upon this short period of remunerative work the practitioner must therefore rely to carry him through the entire year, and with heavy expenses to meet for housekeeping, house rent, servants' wages, taxes, &c., it becomes a serious matter for him when the "season," as often happens, turns out a poor one. He may certainly be able to supplement his winter's income by taking up practice at one or other of the summer resorts, but such practices are difficult to find and with few exceptions are of little value. Failing this he will find nearly the whole summer on his hands, for it is useless to remain at his post during the hot season while his patients have all left to seek the cooler air of the Alps and the Tyrol or have returned to their own country. Nothing is then left for him but to follow their example and thus to incur the heavy expense of moving somewhere else with his whole family. Nevertheless, for a well qualified man with sufficient private means to tide him over the first two or three years, who is possessed of winning manners and supplied with good social introductions, there are always openings where he can still find or create a profitable *clientèle*, although his possible income at any of the smaller health or pleasure resorts will necessarily be a limited one. One word of warning in conclusion. Let anyone who is tempted to buy a practice in Italy proceed with even more caution than he would in negotiating one in his own country. In the first place, the foreign population of nearly all Italian towns is largely a floating one, composed chiefly of people who remain for but a few weeks, often for only a few days in one resort and many of whom never come back again. The vendor of a practice in a place of this sort will have many patients on his books whom he cannot possibly introduce in any way to his successor and a good many others whom he may introduce but who will never return to the locality, or at best do so only at long intervals, and can therefore form no permanent or profitable part of his successor's *clientèle*. His hold upon the practice is, in fact, of a peculiarly personal kind and cannot, in the nature of things, be easily transferred to another. Secondly, the purchaser himself must be a man fitted for this particular class of work, or he may discover too late that he cannot make it pay and that the capital which he has expended has been spent to no purpose. A similar remark is doubtless true with regard to all such transactions, but it applies with special force in the circumstances now under consideration, where the physician has to deal with patients of such varying types and diverse characteristics as are to be met with amongst the travelling public in an Italian health or pleasure resort. To achieve a full measure of success the foreign practitioner in Italy must not only be a man of good all-round attainments, conversant with all branches of his profession, but should be possessed of an unusual share of sympathy and tact, for the exercise of which he will have daily scope amongst patients on whom illness falls with peculiar sadness, alone, as they so often are, and helpless in a foreign land.

---

[1] See THE LANCET, April 28th, 1906, p. 1151, for a full account of the Colonial Medical Service.

GERMANY.

Foreign diplomas are not legally recognised in Germany as entitling their holders to practise medicine, so that British medical men desiring to settle in that country have to attend all the classes and pass all the examinations. A young German before commencing the study of medicine must pass an *Abiturienten-Examen*. That of a gymnasium requires a knowledge of French, Latin, Greek, mathematics, history, and theology. Or the examination of a *Real-Gymnasium* or an *Oberrealschule* may be passed. In the latter event more stress is laid on modern languages, mathematics, and natural-history, and English is required instead of Greek. Foreigners have, as a rule, to pass this examination, but if they have already passed a similar one in their own country they may be exempted from it by a special order to be obtained from the Minister of Public Instruction for each individual case. Medicine can only be studied at a university; the curriculum lasts five years, after the second of which the examination called the *Tentamen Physicum* must be passed; it includes anatomy, physiology, chemistry, physics, and natural history. After the end of the fifth year the student presents himself for the "State Examination," which is practical as well as theoretical, and includes medicine, surgery, obstetrics, gynæcology, pathology, materia medica, and hygiene. After passing the State examination the medical man, having previously obtained his qualification, has to act as clerk and dresser at a university clinic or a recognised hospital. If the medical man wishes to have the title of "doctor" he has to pass another examination, which is little more than a formality, but the degree of doctor without the State examination does not confer the right to practise. The law does not allow qualified British practitioners any exceptional facilities in passing the examinations; the time of study may possibly be made a little less than five years for those who have already studied abroad, but a special order, very difficult to obtain, is always required for this purpose. A thorough knowledge of German is essential. The fees for lectures are at least £130 and the examination fees about £12. The fees for the degree of M.D. vary from £10 to £20, being highest at Berlin University, which is the degree that is most popular with alien medical men. There is sometimes no prohibition set against holders of British diplomas practising in Germany, provided they do not make use of any professional titles resembling those of qualified German medical men. Medical men practising in this way must, however, understand that the law regards them as unqualified, and that they have none of the rights or privileges of the medical profession.

AUSTRIA—HUNGARY.

In order to legally practise in Austria it is necessary to become a naturalised subject, which necessitates five years' residence in the country. The ordinary five years' curriculum of an Austrian University must be attended and if this has been done and the tests have been successfully passed it is unlikely that the naturalisation would be delayed. A holder of a foreign diploma, who is qualified to practise in his own country, may pass the examinations within a shorter time than five years.

Requests for admission to practise in Hungary must be addressed to the Minister of Education who decides upon the conditions of admission after consultation with the Medical Faculty of the University of Budapest. Usually the applicant has to pass three medical examinations, for which a total fee of 225 crowns has to be paid, but this fee is reduced to 60 crowns in cases where the foreign applicant is qualified to practise in his own country. The examinations must, however, be passed.

BELGIUM.

Foreign practitioners must pass the Danish professional examinations.

NETHERLANDS.

A medical practitioner holding British qualifications cannot practise in the Netherlands without being also qualified in the Netherlands. For this purpose it is necessary to pass the medical examinations of one of the universities.

SWITZERLAND.

Foreign practitioners must pass the first, third, and fourth State Examinations. These examinations are held in either French (at Lausanne and Geneva) or German (at Bern, Basel, and Zürich). In addition to the British five years' curriculum practitioners would require one or two years' additional study. The examination fees amount to about £9.

SPAIN.

To practise in Spain or her colonies it is necessary for the holder of British qualifications to send his diplomas to the University of Madrid. After inquiries as to identity a diploma will be sent to the applicant who can then legally practise on the same conditions as a Spaniard—namely, the payment of certain duties.

PORTUGAL.

Holders of foreign diplomas must apply for examination at the schools of Lisbon or Oporto or the Faculty of Coimbra. The cost of the examination, including the diploma, is about £50. For the last examination the presentation of a *printed* dissertation is required.

TURKEY.

Every foreign medical practitioner desirous of settling in Turkey for the purpose of practising his profession must undergo the ordeal of the so-called "colloquium." This is a sort of professional examination very easy in itself but a source of annoyance and vexation to Europeans by the dilatory propensities of orientals and their habit of conducting business in an indolent and easy-going way. "Yavash, yavash" ("No hurry; take matters at your ease"), is the motto of every Turkish official, high or low. The "colloquium" itself takes about half an hour's time, whereas the preliminary steps and arrangements and the subsequent formalities necessary for the final obtainment of the medical permit lasts for weeks and even months. It frequently happens that a certain day and hour are fixed for the examination and that the candidate waits for hours, to be told at the end that there is not the requisite number of professors present to subject him to the test of the "colloquium." This postponement may be repeated twice or even three times and is naturally a matter of trial and irritation to the foreign medical practitioner, especially when he has, probably, to leave the Turkish metropolis at a fixed date to take up the duties of an appointment at a distant part of the empire. It is hoped, however, that matters will improve in every direction, as the whole organisation of the Medical School at Constantinople is undergoing at present important beneficial changes and alterations. To meet, more or less, all the necessary modern requirements a new medical school has been erected at Haidar-Pasha, a district across the Bosphorus, on the Asiatic coast of the Marmora. It is a large stately building, commands a magnificent situation, and is being equipped with all the modern requisites for efficient medical education. In former years foreign candidates were allowed to use the language of their respective countries at a "colloquium," of course with the assistance of an interpreter, but it was found that this concession was taken advantage of by unprincipled persons with no proper medical education, who were thereby enabled to receive a professional permit for practising medicine. The "colloquium" must therefore at the present time be passed either in French or Turkish without any interpreter, the choice of the language being left to the examinee. The possessor of a foreign diploma is tested, as a rule, in four subjects and the testing consists in three or four questions in each subject, which the candidate has to answer orally. It has not yet happened that a European physician failed to pass the "colloquium." The fee for it is about £8 and there are in addition some registration expenses.

RUSSIA.

The law relating to foreign medical practitioners desirous to practise in Russia is contained in the two following paragraphs of the *Vratchebny Ustav* or medical statute:—Section 93 (*a*): No one, whether a Russian subject or a foreigner, who has not a diploma or certificate from a university or from an Army Medical Academy, has the right to follow any branch of medical or veterinary practice in Russia; (*b*) foreign medical practitioners who wish to practise medicine in Russia must, without exception, know the Russian language. Section 94: Of foreign practitioners who shall be invited or who may come to Russia the right to decide which of them shall be permitted to free practice here and under what conditions is in the hands of the Medical Council of the Ministry of the Interior; some shall be permitted only after the usual examinations and consequent granting to them of a learned degree; others more distinguished after an oral examination in the Medical Council; lastly, others who have made a name in the scientific world by their writings or unusually successful practice, or who have occupied professorial chairs or other important medical appointments in other countries, may be permitted to practise without any examination, solely on the decision of the Medical Council, confirmed by the Minister of the Interior, as to the worthiness of such practitioners.[1] Previous residence in the country before practice would not be necessary except in the case of the first group mentioned, who would have to pass through the usual five years' course of a Russian medical curriculum. As to the prospects of a British practitioner in Russia the country and the smaller towns can present no attraction to an English medical man, even if the fees obtainable would support him, which they would not. In the two capitals, Moscow and St. Petersburg, the field is wider. Competition is, however, great, fees are as a rule small, and bad debts many. The frequency of bad debts results from the unwritten law by which medical men do not send in accounts, but leave the patient to pay what he considers a suitable amount.

EGYPT.

Duly qualified British practitioners have no examinations to pass and no fees to pay except a nominal sum for registration. They must, however, exhibit their various diplomas to the Director-General of the Sanitary Department in Cairo and obtain a certificate of good character from the British consul. A knowledge of French or Italian and Arabic would be essential to any newcomer desirous of practising all the year round, for the tourist season only lasts from November to April. Egypt has been a popular place of late with English medical men and there are few or no vacancies for additional English practitioners in Cairo, while the field is already well occupied at Alexandria and the other obvious resorts.

JAPAN.

According to the regulations for medical licence "persons holding either diplomas of foreign universities, or medical schools, or foreign licences for practising medicine may be granted licences for practising medicine in Japan, without being subject to the usual medical examination, upon producing such diplomas or licences obtained in foreign countries to the satisfaction of the home authorities." English medical practitioners will therefore have no difficulty in obtaining a licence in Japan. The fee required for a licence is three yen (about 6*s.*) and with this exception there are no charges in respect of the medical licence. A local rate, which would be a small fee only, may have to be paid on opening a practice. A correspondent informs us that English practitioners in the foreign quarters of Japan are at some disadvantage for the reasons that the druggists, who are now nearly all Japanese, sell their drugs at a cheaper rate to native practitioners, and, moreover, living is cheaper for the native than for the foreigner. Foreign practitioners depend largely upon shipping and contract business work.

---

[1] This Section dates from 1835: it was amended in 1842, 1845, and 1857.

UNITED STATES OF AMERICA.

The laws regulating the practice of medicine in the various States and territories of the United States of America differ to a considerable extent in detail. In spirit, however, they are beginning to assume that uniformity which all medical reformers must desire for them. It has long been pointed out that one of the most open doors to abuse of medical practice in the United States was the fact that while in some States an excellent medical curriculum was required before admission to legal practice, in other States but little scientific training was exacted and freedom to practise was extended to dangerous forms of quackery. This position of affairs had its origin, of course, in the evolution of the United States, certain divisions of the country being in the forefront of civilisation while others were, to say the least, in a rudimentary plight; but of late a great process of levelling-up has been witnessed. The progress of the United States is in no way better shown than in the fact that throughout its vast length and breadth there is now an attempt to secure for the people of the country adequate medical treatment based on scientific grounds. A *résumé* of the legal regulations for medical practice in the States and territories of the United States of America has been published at the office of the *Journal of the American Medical Association*, Dearborn-avenue, Chicago, Illinois. In this digest of the medical laws of the various States, which has been brought quite recently up to date, existing legislation is explained on broad grounds so far as it pertains to medical practice. If the information with regard to some particular State is anywhere scanty in detail it is always possible for the intending practitioner to communicate with the secretary or executive officer of the medical board at the capital of the State.

We must continue to warn the British medical man desiring to practise his profession in the United States of America that in all the more enviable centres he will find a vast number, almost a plethora, of medical men, the great proportion of whom have been thoroughly well educated and trained. He must remember also that in the more important States, generally speaking, although the remuneration may rule high, the expense of living is proportionate. He will understand that the less highly the State is developed the more easy will it be for him to obtain a footing but the less pleasant in all probability will be his professional career. Take, for example, Wyoming. Here the State Board of Medical Examiners recognises as exactly equal "a member of the American Association of Medical Colleges, the Homeopathic Institute, or the National Eclectic Medical Association, or any college of similar standing in foreign countries." Anyone possessing a diploma from one or another of these institutions will receive a certificate from the State Board without examination on payment of $5. Certainly there is not much bar to medical practice by the British qualified medical man, but as the door is widely open at the same time to members of "any college of similar standing" to the National Eclectic Association it will be seen that not much distinction is attached to the licence. Similar views will be found prevailing in, among other States, Wisconsin, where the board of medical examiners used to include not only homœpaths but two eclectics and one osteopath, and we have not heard that it has become more select We mention this to show that it is necessary for a British medical man, who desires to practise his profession in the United States of America, to obtain full information before taking action by writing to the medical board of the State selected.

CANADA.

The Canada Medical Act, 1902, authorises the creation of "The Medical Council of Canada" (but it is not in force yet owing to the Quebec Legislation having refused to ratify it), with power to establish a qualification in medicine entitling holders thereof to practise in all the provinces of Canada, but no regulations have as yet been issued. As a general rule, the possession of British diplomas and degrees entitles the holders to practise in Canada after having obtained a licence from the provincial medical boards and paid certain fees.

Prince Edward Island.—No one can practise medicine, surgery, or midwifery in Prince Edward Island unless registered or licensed by the Council of the Medical Society of Prince Edward Island. The Council admits upon the register any person who is duly registered by the General Medical Council of Great Britain.

New Brunswick.—Practitioners in New Brunswick must be registered by the Medical Council of the province. A candidate for registration (1) must pass an examination in English, arithmetic, algebra, geometry, Latin, elementary mechanics, history, geography, and two of the following languages, Greek, French, and German, unless he has already matriculated at some college in the United Kingdom, Canada, United States of America, or Europe, or holds a first-class teacher's licence from the Board of Education of New Brunswick; (2) he must afterwards have studied for four years and attended some university or college or school of medicine for four sessions of not less than six months each and have attended lectures on anatomy, pharmacy, &c.; (3) he must have attended the general practice of a hospital for 12 months; (4) he must have obtained a degree in the above subjects from a university, college, or school requiring such four years' course of study or must have passed an examination in them before the examiners in New Brunswick; and (5) he must be over 21 years of age. A fee of $10 is required and medical practitioners are liable to an annual fee of from $1 to $2.

Nova Scotia.—Registration and a licence from the Provincial Medical Board are required, which admits upon payment of the registration fee all persons who are duly registered by the General Medical Council of Great Britain.

Quebec.—Practitioners must be licensed and registered by the Provincial Board, which may license without examination holders of medical qualifications from British universities or corporations.

Ontario.—Registration by the Council of the College of Physicians and Surgeons of Ontario is necessary and it is optional for the Council to admit to registration all persons who are duly authorised to practise medicine, surgery, and midwifery in the United Kingdom and Ireland upon terms which the Council may deem expedient.

Manitoba.—Registration by the Council of the College of Physicians and Surgeons of Manitoba is necessary and applicants for registration must be members of an incorporated medical body in Canada giving similar privileges to persons incorporated in Manitoba. Application should be made to the Council by British medical men desiring to practise in the province. Licences to practise are issued to women upon the same terms as men.

North-West Territories.—Any person possessing qualifications from any university or corporation in Great Britain or Ireland is entitled to practise medicine and surgery, on production of the testamur and on proof of identity, after registration by the Medical Council (the Registrar's office is at Calgary). The annual membership fee is $2 and the fee for registration is $60. Licences to practise are also issued to women.

British Columbia.—No person may practise medicine, surgery, or midwifery in British Columbia unless registered by the College of Physicians and Surgeons of British Columbia. The Council admits to the register any person "who shall produce from any college or school of medicine and surgery, requiring a four years' course of study, a diploma of qualification," on proof of identification and on passing an examination as to his competency. The fee for registration appears to be rather indefinite, as we learn that it "must not exceed $100" and the annual fee is from $2.50 to $10. Licences to practise are issued to women.

AUSTRALIA.

Legally qualified British medical men can practise in all parts of Australia. Proof of registration by the General Medical Council of Great Britain must be submitted to the medical board of the particular State selected when a certificate to practise is granted. The medical man with British qualifications who desires to practise in Australia must communicate with the medical board as soon as he intends to settle, so that he may regularise his position from the beginning.

NEW ZEALAND.

Registration in the colony of New Zealand is obtained by the legally qualified British practitioner on producing his proof of registration by the General Medical Council of Great Britain and on paying a fee of £1 5s.

BRITISH SOUTH AFRICA.

The position of the legally qualified British practitioner in

South Africa is much the same whichever colony he proposes to practise in.

Cape Colony.—No person may practise in Cape Colony as a medical practitioner without a licence signed by the Colonial Secretary of the province and the recommendation of the Colonial Medical Council is required. The fee for the licence is £5 and women are eligible for the licence. Applications should be made to the Colonial Medical Council at Cape Town.

Natal.—Here also application for a licence to practise medicine in the colony must be made to the Colonial Secretary of the province. The application will be granted upon the approval of the Natal Medical Council and the fee for registration in Natal is one guinea.

Southern Rhodesia.—The admission fee for the practice of medicine in Rhodesia is £5 and application for the licence should be made to the Administrator of Rhodesia at Salisbury, Rhodesia. It would be well also to write to the Secretary of the British South Africa Company, London Wall, E.C.

Transvaal and the Orange River Colony.—The Transvaal Medical Council (Pretoria) and the Medical and Pharmacy Council of the Orange River Colony, Bloemfontein, grant a licence to practise on payment of £10 and £7 10*s.* respectively. Proof of registration by the General Medical Council of Great Britain must be supplied.

THE COLONIAL MEDICAL SERVICE

In the following countries there are medical departments regulated from the Colonial Office:—British Guiana, Jamaica, Trinidad, Tobago, Windward and Leeward Islands, British Honduras, Fiji, Ceylon, Straits Settlements, Federated Malay Straits, Hong-Kong, Mauritius, Seychelles, Gibraltar, St. Helena, Falkland Islands, Gambia, Sierra Leone, Uganda, the Gold Coast, Lagos, and Northern and Southern Nigeria. The last six of the countries enumerated have been formed into the West African Medical Staff, a definite and well-organised service. The particulars of the Colonial Medical Service were published in full in THE LANCET, April 29th, 1905, p. 1151, and all information concerning any vacancies in the service can be obtained from the Colonial Office.

THE IMPORTANCE OF VITAL STATISTICS.

WE have on a previous occasion pointed out that it would be greatly to the advantage of the medical profession and the public if our practitioners enjoyed a more intimate acquaintance with such of the methods of statistics as are appropriate for medical purposes. We do not for a moment propose to oppress further the already overburdened medical aspirant by requiring him to master the intricaces of the integral or differential calculus. The construction of life tables could scarcely have been perfected without the help of higher mathematics, but the necessary calculations have already been elaborately worked out by the late Dr. Farr, the acknowledged founder of the science of vital statistics, and Dr. T. E. Hayward of St. Helens has recently published detailed instructions, with mathematical formulæ, for the compilation of shortened life tables. With the aid of these a medical officer of health of average ability may readily construct a life table for his own district. A fair working acquaintance with ordinary arithmetic and algebra, and especially with logarithmic calculations, will furnish the medical student with most of the mathematical equipment that he is likely to need; but within these limits he should certainly be versed in the ordinary "technique" of vital statistics and should be familiar with the application of statistical methods to the solution of the everyday questions of preventive medicine.

Of text-books on vital statistics there is fortunately, no dearth. The well known manuals of Newsholme, Whitelegge, and Hamer, especially the first mentioned, will supply the student with the necessary instruction. But perhaps the most useful information within a moderate compass for the student of medicine will be found in the article on Medical Statistics included in the first volume of the new edition of Professor Allbutt's "System of Medicine." This article is contributed by a well-known authority on the subject, and as volume I. contains in addition useful essays by recognised experts in climatology and on the geography of disease it will be appreciated by the medical student as well as by the practitioner, both of whom need such information in a trustworthy and an assimilable form. The extent of statistical proficiency required for medical purposes is specified in each of the books just referred to, but for those who desire to pursue further the study of general statistical science the work of Mr. A. L. Bowley may confidently be recommended.[1] We would, however, utter a note of warning against indiscriminate reliance on so called "statistical statements" in the discussion of medical problems. It has been often contended against the use of numerical methods in questions of this kind that "anything may be proved by statistics." To this the obvious retort is that "without statistics you can prove nothing." It is not in the legitimate use, but in the abuse, of statistics that the real fault lies—in endeavouring to strain from mere collections of figures conclusions which they are not fitted to support. Mr. Bowley speaks of statistics as "the science of counting." "Counting," he says, "appears at first sight to be a very simple operation. But, as a matter of fact, when we come to large numbers—e.g., the population of the United Kingdom—counting is by no means easy ...... and in no way can absolute accuracy be attained when the numbers surpass certain limits. Great numbers are not counted correctly to a unit, they are *estimated*, and we might, perhaps, point to this as a division between arithmetic and statistics, that whereas arithmetic attains *exactness* statistics deal with *estimates*, sometimes very accurate but never mathematically exact. ...... Statistics is rightly defined as the science of averages. Out of a great number of men the *type* is found—the average, about which all measurements are grouped according to some definite law. The problem is, then, to determine whether the type or the grouping about it changes and in what way. ...... Great numbers and the averages resulting from them have great *inertia*. The total population, the total income, the birth and death-rates, *change very little*. Similar quantities relating to a single family change very fast. It is this constancy of great numbers that makes statistical measurements possible." Mr. Bowley then goes on to contrast statistics with arithmetic in the application of both to demography. "In a monograph a single family is studied: the occupation, the earnings of its members, the way these earnings are spent ...... are set down, but this study is not, so far, statistical. In demography we study the same quantities when groups of families are concerned; the number of families engaged in certain industries and their average receipts, expenditure, and savings —here we have statistics. In the monographic method the individual is everything; in the statistical method, nothing."

With respect, more especially, to statistics of mortality, it should be realised, *in limine*, that the individual facts with which we have to deal are by no means of uniform value. Take, for example, the returns of death from malignant disease. It is obvious that greater accuracy must attach to the diagnosis of, say, 100 cases of cancer in a hospital where the clinical diagnoses are tested by microscopical aid during life, or by post-mortem examination, than would attach to the diagnosis of the same number of cases occurring in country houses where necropsies are extremely rare. Again, as regards the ages at death, it is notorious that the registers are very untrustworthy. In many cases the ages of old people are unknown, and in all cases the statement of age in the registers is derived from the relatives of the deceased, who, for purposes of life insurance, are sometimes interested in concealing the truth. And it is to be feared that the published statistics of mortality are not infrequently vitiated by the act of the local authorities who, although prompt to exclude from their returns the deaths of strangers occurring within their domains, show no corresponding anxiety to include the deaths of their own residents should they occur outside the district boundaries. We need not go further into the various advantages attending a study of right statistical methods, or detail other openings for statistical fallacies; we will conclude by conveying to our readers the assurance that the acquisition of the power to understand arguments drawn from figures can only be fully attained by a certain amount of special work in the desired direction.

---

[1] Elements of Statistics, by A. L. Bowley. P. S. King and Son.

LITERARY INTELLIGENCE.—A new volume for students will be published on Sept. 5th by Messrs. J. and A. Churchill entitled "A Short Practice of Medicine," the author being Dr. R. A. Fleming, lecturer on the principles and practice of medicine at the Edinburgh Medical School. The volume is a large one, as the work is intended to be comprehensive, and some of the illustrations will be in colour. A large sale is evidently expected, as the moderate price of 10*s.* 6*d.* will be asked.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students we are necessarily compelled to defer the publication of communications on other important subjects.

We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based. We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies may be found.*

TO ADVERTISERS.

Owing to the pressure on our advertisement columns this week some announcements have unavoidably been held over.

Communications, Letters, &c., have been received from—

A.—Dr. B. Anningson, Cambridge; Messrs. Arnold and Sons, Lond.

B.—Dr. F. T. Bond, Gloucester; Messrs. David Bryce and Son, Glasgow; Mr. J. W. Benson, Lond.

C.—Mr. E. R. Haines Cory, Bournemouth; Dr. L. P. Colat, Tsivory, Madagascar; Messrs. J. and A. Churchill, Lond.; Messrs. Cosenza and Co., Lond.; Messrs. Cassell and Co., Lond.; Messrs. T. Cook and Co., Lond.; Messrs. E. Cook and Co., Lond.; Messrs. S. Clark and Co., Lond.; Mr. F. W. Clarke, Chorlton-cum-Hardy.

D.—Mr. S. M. Dodington, Henstridge; Messrs. Dawson and Sons, Lond.

E.—East Suffolk Hospital, Ipswich; Eccles and Patricroft Hospital, Secretary of.

F.—Mr. G. Fingerhut, Lond.; Messrs. Ferris and Co., Bristol; Mr. J. FitzGerald, Queenstown; Messrs. Folkard and Hayward, Lond.; Messrs. Foster, Brown, and Co., Montreal; Mrs. Fryer, Lond.

G.—Mr. R. Groves, Lond.; Glasgow Eye Infirmary, Secretary of.

H.—Mr. W. G. Humphrey, Lond.; Colonel F. Howard, R.A.M.C., Lond.; Mr. S. Harvey, Lond.; Messrs. Haasenstein and Vogler, Cologne; Dr. P. W. Hampton, Wigan; Hull Advertising Agency, Manager of.

J.—Mr. W. Judd, Lond.; Messrs. W. and A. K. Johnston, Edinburgh.

K.—Dr. Arthur Keith, Bredgar; Mr. R. C. B. Kerin, Bourne End.

L.—Mr. H. K. Lewis, Lond.; Messrs. J. Lang and Son, Lond.; Dr. Isabel Logie, Newport-on-Tay; Dr. W. Lane, Weymouth; Messrs. Lee and Martin, Birmingham; Messrs. Lee and Nightingale, Liverpool; Messrs. Larcom and Veysey, Lond.; L. M. D.

M.—Professor E. A. Minchin, Lond.; Mr. N. Mayne, Longford; Medical Society of Victoria, Melbourne, *Hon. Treasurer of*; *Medical Fortnightly*, St. Louis, U.S.A., Managing Editor of; Mr. R. McCowen, Tralee; Male Nurses' Temperance Co-operation, Lond.; Mr. E. Merck, Lond.; Manhu Food Co., Liverpool, Messrs. Maconochie Bros., Lond.; Mr. T. Bingham Marshall, Lechlade; Mr. S. B. Mason, Pontypool; *Midland Counties Herald*, Birmingham; Dr. F. S. Mackenzie, York; Messrs. Max L. Schultze and Co., Peterhead.

N.—Mr. F. W. North, Grantham; Mr. Reginald Nitch-Smith, Lond.; Noise Abatement Committee, Lond., Hon. Secretary of.

P.—Mr. Y. J. Pentland, Edinburgh; Mr. L. Posse, Lond.; Mr. C. F. Price, Malvern; Messrs. Parke, Davis, and Co., Lond.; Dr. F. J. Poynton, Lond.

R.—Dr. B. G. Robson, Jodhpur, India; Mr. Horace W. Randall, Southend-on-Sea; Dr. A. G. Silva Rodrigues, São-Paulo, Brazil; Dr. J. C. S. Rashleigh, Okehampton; Messrs. Reitmeyer and Co., Lond.; Mr. J. W. Root, Bournemouth; *Reading Mercury*, Manager of; Miss E. M. Routledge, Newport; Messrs. E. J. Reid and Co., Lond.

S.—Mr. Henry Smith, Egremont; Messrs. Squire and Son, Lond.; Messrs. Spiers and Pond, Lond.; Messrs. Smith, Elder, and Co., Lond.; Messrs. Sharland and Co., Auckland, New Zealand.

W.—Dr. F. J. Woollacott, Lond.; Messrs. J. Wright and Co., Bristol; Mr. H. B. Wilkinson, Blackadon; Messrs. Warner, Sheppard, and Wade, Leicester; Dr. Clifford White, Lond.; Mr. C. E. G. Walker, Dewsbury; Mr. W. H. Griffin Wilkes, Walsall; Mr. A. Willmott, Lond.; Mr. V. Wood, Lond.; Wand Manufacturing Co., Leicester; West Bromwich District Hospital, Secretary of; W. P. G.; Messrs. W. Wood and Co., New York; Messrs. H. Wilson and Son, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. F. N. Allen, Crookes; A. P. A. E.; A. G.; Aberdeen City District Lunacy Board, Secretary of; Ashton-under-Lyne District Infirmary, Secretary of; Messrs. Armour and Co., Lond.

B.—Mr. C. A. G. Browne, Lond.; Mr. E. Birchall, Birmingham; Dr. J. Biernacki, Plaistow; Dr. J. H. Bell, Lochranza; Messrs. W. H. Bailey and Son, Lond.

C.—Dr. C. S. Crichton, Newton; Messrs. Curling, Wyman, and Co., Lond.; C. S. B.; Messrs. Carruthers and Son, Inverness; Messrs. Cleaver and Co., Lond.; C. G. P.; C. W.; Messrs. J. and A. Carter, Lond.; Mr. C. Colat, Bordeaux.

D.—Mr. G. F. Darker, Lond.; Dr. H. Davies, Lond.

E.—Mr. F. G. Ernst, Lond.; E. N. T.; E. B. M.

F.—Professor A. Fraser, Dublin; Mr. F. T. Fagge, Buxton; F. E. F.

G.—Dr. P. Goold, Macroom; Glasgow Royal Infirmary, Secretary of.

H.—Mr. J. Heywood, Manchester; Mr. R. R. Harper, Lond.; *Dr. T. B. Heggs*, Sittingbourne; Messrs. T. Holland and Son, Lond.; Mr. J. Hart, Lond.; Mr. W. H. Hunt, Lingfield; H. G. B., Lond.; Messrs. Hill and Hoggan, Glasgow.

I.—International Plasmon, Lond.

J.—Dr. M. Joannides, Nicosia, Cyprus; J. H. G.; J. W. P.; J. A. C.

K.—Mr. R. V. Khedkar, Edinburgh.

L.—Staff-Surgeon G. Ley, R.N., Channel Fleet; L. C.

M.—Mr. G. B. Messenger, Lond.; Dr. J. B. McCutcheon, Blaengarw; Messrs. Manlove, Alliott, and Co., Nottingham; Dr. J. Moore, Enfield; Mr. W. Morgan, Lond.; Medicus, Chorlton-cum-Hardy.

N.—Dr. A. Noble, Luthermuir; Northern Medical Association, Glasgow; N. G.; N. T.

P.—Mr. C. M. Perry, Leatherhead; Dr. W. P. Panckridge, Petersfield; Miss Perkins, Lond.; Plymouth Borough Asylum, Blackadon, Secretary of.

R.—Mr. J. Randall, Liverpool; Dr. A. Maitland Ramsay, Glasgow; R. W.

S.—Mr. D. Sen, Malda, India; Standard Emulsion Co., New York; Dr. D. Shannon, Glasgow; St. John Ambulance Association, Lond., Secretary of; Mr. J. Sampson, York.

T.—Mr. Hugh Taylor, Llandovery; T. J. D.; T. M. C.; Dr. J. Taylor, Lond.

V.—Velox, Cardiff.

W.—Mr. J. Williams, Bradford; Captain R. H. Willis, R.M., Gosport; Messrs. Willows, Francis, Butler, and Thompson, Lond.; Dr. W. K. Walker, Glasgow.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, *London, to whom* all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout *the United Kingdom*. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

Presidential Address

ON

THE EVOLUTION OF INSANITY.

Delivered before the Medico-Psychological Association of Great Britain and Ireland at the Sixty fifth Annual Meeting, held in London on July 26th, 1906,

BY ROBERT JONES, M.D. LOND.,

RESIDENT PHYSICIAN AND SUPERINTENDENT, LONDON COUNTY ASYLUM, CLAYBURY.

[Dr. Jones in his introductory remarks, after thanking the association for his election to the position of president, said that each president who had occupied the chair annually during the last 20 years in succession was still living. (Dr. Oscar T. Woods, who was president in 1901, has, however, died since the delivery of Dr. Jones's address.) In his references to the history of insanity in ancient times he mentioned early Egyptian allusions, the Biblical accounts of Saul, David, and Nebuchadnezzar, and mediæval views with regard to demoniacal possession. He said that during the Middle Ages over 100,000 persons were stated to have been put to death for witchcraft and sorcery, of whom about one-third were lunatics. He then spoke of the mediæval treatment of the insane in Great Britain by various herbal remedies, holy water, and holy wells, such as those of St. Winifred in Wales, of St. Maree in Ross-shire, Great Nun's Pool, St. Fillan's in Perthshire, and St. Ronan's near the Butt of Lewis. He then continued as follows:—]

I have selected as my subject the Evolution of Insanity, or more exactly the evolution of our conception of it, both as regards the special forms of mental disorder and the evolution also of their general treatment. It is not a little remarkable that whereas in former times various restraints and penalties were applied to the patient it is now the physician who is threatened with penal clauses and surrounded with restrictions. He has no power to treat under his own roof for payment any case in the early uncertified stage of incipient mental disease, the stage when treatment is most likely to be successful. If he receives such a patient—even his own brother or other relative—to board and lodge with him he is guilty of a misdemeanour and is liable to be fined £50. He is not permitted to receive any case of insanity unless certified and if he receives two or more patients, although they may be certified, he is again liable to be charged with misdemeanour. Moreover, if he has himself certified any patient to be insane he is debarred in consequence from applying to that patient his own counsel and treatment. In mentioning these particulars I am merely stating what the law is and am not suggesting that these restrictions are all of them improper.

The first custodial institution for the care of the insane was founded in Florence in 1389 and this was followed in 1403 in our own country by the establishment of "Bethlem"; subsequently in 1660 the Hôtel Dieu in Paris was opened and in 1737 an institution was established in Pennsylvania. Shakespeare makes frequent reference to insanity and during the two centuries which elapsed from his death until 1815, when an inquiry was held before a committee of the House of Commons, the treatment of the insane was accompanied by flagellation, torture, confinement in dark rooms, and acute suffering, often until death released them. The insane were tied to crosses or to pillars in churches, they were flogged at "trees of truth," and they were burnt at the stake as sorcerers. They were fastened in chains, strapped in covered cribs, and confined in wristlets and strait jackets even in our own country so late as the year 1841. The harsh measures of the eighteenth and early nineteenth century included also severe and unsympathetic medical treatment, such as blood-letting in the standing, recumbent, or sitting posture; active counter-irritants; drastic purgatives; the shower bath; emetics; and heroic doses of tartarised antimony, of mercury, and of digitalis. These have now given way to hygienic measures, exercise, and suitable medicinal and moral treatment of which congenial occupation and amusement form especial features.

It was only during the nineteenth century that lunatic asylums underwent the metamorphosis which has resulted in their present excellent condition. As a contrast to the gaols, shrines, holy wells, chains, tortures, and exorcism, we have to-day suggestions for the care and cure of early cases of insanity by "reception houses," and we already have well-planned and furnished hospitals for the acutely insane, others for the chronic insane, asylums for the criminally insane, institutions for inebriates or chronic drunkards and for the feeble-minded, and finally we have colonies for the epileptic.

Previously to the Gordon Ashley Act of 1828 there were but few legal enactments dealing with the care of the insane, those existing at this time dating back only to the second or third year of the reign of William IV., although the Lunacy Commissioners inform me that statistics may be traced as far back as the reign of Edward II. Prior to 1828 the Royal College of Physicians of London, represented by five of its Fellows, had the supervision and licensing of asylums in London and Westminster within a radius of seven miles, whilst the county justices of Middlesex and other counties acted for the provinces, a supervision which was not to the advantage of the insane. In the year referred to the number was augmented to 15 Fellows of the College and in 1832 this body was styled the Metropolitan Commissioners in Lunacy. In 1842 they were accorded the duty of visiting the public asylums of England and Wales and the whole of their report for this year extended to only one and a half pages. In 1845 the present board of 11 Commissioners in Lunacy was appointed, five of whom are honorary. It was not until Jan. 1st, 1859, that the number of lunatics was officially registered in this country. At that date there were 36,762 insane persons, a proportion of 1 to every 536 of the population. The number of registered insane persons in England and Wales when the Lunacy Commissioners were first appointed was 11,272, there being then only 15 county asylums. Last year (1905) there were 119,822 and a total of 88 asylums. The report of the Lunacy Commissioners has also grown from a page and a half to a volume of over 500 pages. This record would not be complete without some allusion to the more recent legislation for the idiot and imbecile. Up to 1847 no separate provision existed for this class, but Dr. Andrew Reed—a philanthropic divine—began to interest himself in this class and subsequently founded the Earlswood Asylum, from which as a pioneer sprang several other most deserving and useful charities. In 1886 an Act was passed permitting backward children to be placed in such institutions upon one medical certificate, merely stating that such a course would benefit the child, so that it is now no longer necessary to certify these backward children as "lunatics." We have further for children less afflicted the Epileptics and Defective Children's Act of 1899, making it permissible for public authorities to provide suitable educational faculties for this class. The number of mentally and physically defective children on the roll and actually attending the special schools for London has been kindly given to me by Dr. James Kerr and they are as follows: "Average attendance at elementary schools is 666,757 and at the special schools 5831 (mentally defective 4522, physically defective 1309). The full roll is 757,084 and 6952 respectively (mentally defective 5311, physically 1641), giving an average of almost 1 per cent. of defective children attending the special schools in London alone." Dr. Kerr further states "that there are probably as many more children mentally and physically defective who are not so classed."

Now many of the vagrants, ne'er-do-wells, profligates, and immoral persons, criminals and lunatics, are recruited from these classes, and in my own experience cases are received into asylums from prisons who have in infancy attended hospitals and charities as mentally and physically defective. If the stock is to be kept free from taint a proper supervision should be kept over this class. In country districts they are more definitely known and a certain amount of "communal vigilance" is exercised over them, but in towns this is obviously impossible, and it should become the duty of the State so to register them by special notification through the schools as to direct and control their lives and to see that adequate care is exercised over their destinies in specially adapted schools, homes, colonies, or settlements. Such a regard would tend to lessen the necessity for increased asylum accommodation; but to this we shall refer later.

Among the various contributory factors to the changes in the treatment of the insane, one is the recognition of mental diseases as an integral part of disorders of the nervous system and not a fragment detached as it were from the domain of general medicine. Possibly also the mental infirmity of King George III. gave an impetus to the more enlightened treatment of mental diseases, which even long after this period continued to be a reproach. The fact that all institutions for the care of the insane are carefully inspected by Government officials of recognised professional ability and rank in law and medicine, whose reports are made public, has had a great effect upon the care of the insane, as also the fact that they are for the most part supervised by unsalaried boards of trustees representing charities or by managers and visitors elected by the people; and I think we may legitimately claim the further fact that institutions for the insane are served by responsible medical authorities who link their reputations with those of the institutions they serve and to which they devote their time with loyal energy and fervour.

There is in consequence of the above reasons more confidence on the part of the public who are now ready to send into these institutions all mentally infirm persons from whatever cause; more especially do we now find old people admitted who are suffering from the decay of nature and whose friends no longer have the necessary time, the accommodation, or the means to supervise them—cases which in the circumstances of the past would have been retained by their relatives in their own homes. Upon this point, going back to 1859, we find that 56 per cent. of all pauper lunatics were in asylums, the rest being in workhouses or with their friends. In 1905 over 78 per cent. were in asylums, showing among other causes that probably the capitation grant of 1874 may have had the effect of sending into asylums a large number of chronic and incurable patients formerly detained in workhouses and kindred institutions. Most of these cases, in spite of their transference in a state of senility and infirmity, owing to their improved sanitary surroundings live longer and therefore tend to accumulate in our asylums. Added to these senile cases there is an increasing number of young people who being mentally defective (and this defect is now recognised by law) are, whilst children, looked after and cared for at home and in special schools, but as adolescence approaches and they begin to give trouble they are brought into our asylums. Most of these cases, owing to the very nature of their affliction, are incurable from the start and they help to form the chronic remainder of hopeless cases. There is no doubt that this burden of the incurable insane is growing fast and that fresh accommodation is constantly being called for.

Surely the voice of our association should be clamant as to some remedies when more than 1 in every 285 of our population is an inmate of an asylum and when there are already over 120,000 certified insane persons in England and Wales; when, moreover, there is an equal number of potential lunatics, those not known to us by certification—namely, weak-minded and neurotic persons out of whom lunatics are recruited owing to a vicious inheritance or to a wretchedly sordid environment. Furthermore, the pauper roll has latterly been a growing one, as is shown by the report of the Local Government Board on poor relief in England and Wales during the half year ending Michaelmas, 1905, which exhibits the steady increase of the cost of pauperism, particularly in London, an increase on the corresponding half year of 3·1 per cent. for England and Wales. It was stated that during the year 1900 in the United Kingdom 1,882,000 persons sought poor relief and of these about half a million were over 65 years of age. On Jan. 1st, 1905, there were 932,267 pauper persons in England and Wales, an increase of 63,139 compared with the previous year. This is equal to about 1 in 37 persons, or 2·7 per cent. of the whole population of England and Wales, being a pauper person dependent upon the earnings of others. My own country (Wales) is the most distressful in the three kingdoms in this respect, having an average of 3·11 per cent. of the total population who are paupers, Scotland with customary superiority having the least number. The total cost of relief to the poor during the year ended Lady Day, 1904, for England and Wales was £13,353,656, an increase upon the previous year of £405 333 The latest information from the Local Government Board department shows that £36,264,702 were spent upon pauper lunacy from 1880 to 1904 inclusive. The result of the last two census returns also shows that whereas in 1880 there were only 65,345 pauper lunatics in England and Wales, in 1905 there were 109,100—an increase of 49 per cent., whilst the population during the same period has only increased 25 per cent. In the quinquennium 1880–84 inclusive the annual average expenditure upon intoxicating liquor in the United Kingdom was £143,799,641; in the quinquennium 1900–04 it was an annual average of £177,920,339—an increase of 24 per cent., whereas the population of the United Kingdom has increased by only 19 per cent.

With regard to the causation of insanity we know that heredity plays a most potent part. A history of insanity in the ancestors determines a tendency to this in the descendants. We also know that the spread of venereal disease is responsible for increasing certain forms of insanity which are of a most hopeless character as to recovery and that over-stimulation in many directions induced by modern social conditions contributes to insanity. Intemperance in the use of alcohol is well known to be a contributory factor and statistics collected from many sources and for a long term of years present an almost unchanged average incidence of insanity through alcohol. An average of 22 per cent. of men and of 10 per cent. of women who are insane in the county of London owe their insanity to alcoholic excess.

Attention may be specially called here to the diminishing birth-rate as further evidence of the love of selfish pleasure and the shunning of parental responsibility incident upon so-called progress, and not only is there a diminishing birth-rate but unconnected with this marriages are contracted later. In 1901 the birth-rate for England and Wales was 28·5 per 1000 living, then the lowest rate since the civil register was established, and 1·4 per 1000 below the mean rate in the ten years immediately preceding. In 1905 this had further fallen to 27·6, whilst for London the rate had fallen to 27·1 per 1000. This rate has been declining for many years but never before 1898 had it fallen below 30 per 1000. Civilisation means the association of men and women in towns which only the rich can circumvent, wealth enabling this class to live out of the towns. City life means artificial desires and their gratification, but civilisation also implies progress which proceeds at the expense of the less fit—a higher standard is fixed and those who are unable to attain it are left behind to sink lower and lower. The population of the convict and local prisons shows an increase in 1905 of 9447 persons as compared with the previous year.

I do not think that I am called upon to notice the asseverations of angry pamphleteers in the public press. When, however, a journal of the reputation of the *Times* (April 14th and 21st *et seq.*) takes up this question it is bound to arouse attention. The growth of insanity is undeniably a matter of considerable public importance and few subjects have of late more employed the pen of every class of critic than the legal, curative, custodial, and even the preventive aspects of insanity. Overdrawn and unjust statements have been made in the *Times* that the insane to-day are under the care of officials who have neither received the necessary training for conducting scientific investigations nor have the inclination to pursue them. Medical officers of asylums are stated to be physicians only in name, for they neither devote thought nor time to professional work. The asylum service is held up as a scarcely conceivable career for a young man of promise or for a person of real capacity. Moreover, it is stated to be a service which has practically excluded insanity from the area of scientific investigation. In short, asylum medical officers are in these articles actually held responsible for the accumulation of incurable insanity in our asylums, a state of things which implies a grievous burden upon the community. It is then suggested that a special hospital would render unnecessary "the provision of a constantly increasing number of huge buildings for the life-long incarceration of thousands of men and women who are now annually suffered to drift into hopeless incurability" and who accumulate *ex hypothesi* from the failure of asylum physicians to cure them.

Now if these statements are true and if the reduction of the blot and burden of insanity can be thus relieved I am able from this presidential chair and with the unanimous voice of this association to promise the scheme our most cordial support, but although I should welcome the continuous and direct assistance of hospital physicians in our work I feel that they can no more prevent the occurrence of incurable insanity than they can prevent the filling up of cemeteries. It may be recalled that Sir William Gull over 40 years ago was medical superintendent of the insane wards of Guy's Hospital. He had charge of the insane cases in that hospital and had the advantage in their treatment of the services of the medical officer hospital physicians and surgeons. Yet what happened? The Lunacy Commissioners considered that the patients were less favourably placed there than those who were in asylums, and the hospital authorities, *in the interests of the insane*, were compelled to close the wards. Is the treatment of insanity in this country to-day the shame and reproach which our critic asserts? I venture to think these statements are not only inaccurate but they are also detrimental to the position we claim to hold in the larger medical world outside our asylums and I purpose very briefly to refer to this aspect.

[Dr. Jones here discussed in some detail questions of medical treatment in asylums as well as recovery-rates and death-rates at various times and places. He then continued as follows:]

Having analysed the recovery-rate and noticed its fall within recent years let us now compare the varieties of insanity as they are known to-day with those of which we had knowledge a century ago. Of these epilepsy appears to have undergone but little change and remains intractable in regard to cure. General paralysis, on the other hand, has become more common. John Haslam early in the last century was the first to describe this disease, although Esquirol had already noted the extreme gravity of those cases in which dementia was complicated with paralysis. Dr. T. S. Clouston refers to deaths among women from this disease during an experience of over 30 years. In the first decade of his experience 7·5 per cent. of the deaths among women under his care were from this disease, in the second the percentage had risen to 9·7 per cent., and in the third decade to 12 per cent., whilst in the following year (1904) the deaths from general paralysis among women had risen to 23·5 per cent. In my own experience for 1905 at Claybury a proportion of 36·5 per cent. of the total deaths were from general paralysis of the insane. The time of onset of general paralysis after syphilitic infection appears also to be shorter than formerly. In a recent average the period is given as about ten years, whereas past records give an average of 15 years, a fact which tends to show one of two things—namely, either a diminished resistance of the individual to the effects of competition or an increased "stress" through the conditions of modern life in which the stimuli are both more numerous and more complicated. It is certainly not syphilis alone which is the cause of general paralysis, for in the insane population of the Straits Settlements Dr. W. G. Ellis, a competent observer, states that general paralysis is exceptional there, although syphilis is rampant; probably the Malay race has not reached the stage of evolution in civilisation at which "stress" is felt. It is further asserted by those in a position to form a judgment (and Sir Alfred Cooper is of this opinion) that syphilis is not more common to-day than it was a century ago, although general paralysis appears to be on the increase.

Dementia præcox seems formerly to have been rare but it is now so common that it attacks prematurely our most promising and educated youth, the brain worker rather than the manual labourer, young men rather than women, and it is a disease so incurable that it tends to fill our asylums with hopelessly insane patients. Haslam refers to it as "a species of insanity sometimes occurring about the time of puberty, especially in those who have possessed a good capacity, a lively disposition, and in females more than in males. Their faculties are gradually obliterated until they are at last complete and incurable idiots." Although premature dementia, as such, is not referred to in the Lunacy Commissioners' report, the statistics for the last quarter of a century support the assertion that it is more common than formerly. These cases almost invariably commence in depression and it is justifiable to conclude that they were classed as melancholia, which has risen from 21·5 per cent. of the total admissions in 1678 to 31·2 per cent. in 1904. Cases of mania, on the other hand, have diminished from 53·8 per cent. of the total admissions in 1878 to 40·3 per cent. in 1904. Senile insanity, which shows the wreckage due to long-continued stress, has apparently undergone a remarkable increase, partly due, it is acknowledged, to increased registration. In some districts senile, or I would prefer to call it pre-senile, insanity has increased from 11 to 20 per cent. of the total admitted into asylums within the last 16 years and the evidence given by Sir John MacDougall before the Commission on the Feeble-minded confirms the increase in this form. The congenital varieties of mental deficiency show but little increase according to asylum statistics. These are teratological variations not controlled by any natural laws and they make themselves apparent by arrest of development often accompanied by physical stigmata. These varieties, which exist in every country and among every race, are the least reflection upon civilisation. They occur among the lower animals and are familiar to all observers of comparative natural history.

[Dr. Jones here mentioned some views held in the eighteenth century as to the causation of insanity and expressed sympathy with the advocates of "Eugenics." He then proceeded as follows:]

The highest function of medical science is the prevention of disease—i.e., the adoption of special measures which are known through experience to be protective against injurious influences; and of all known diseases there is not one in which there is either a greater need of prevention or one which permits of more effectual limitation by precautionary measures when taken in the early stages than insanity. Hence we need statutory authority to treat incipient insanity as other diseases are treated—namely, with full freedom to the physician *and proper and adequate safeguards* for the interests of the patient. Such means would prove to be a most valuable auxiliary towards prevention. I am of opinion that those who undertake the care of the insane in the incipient stages should be especially sanctioned by recognised authority so to do; but I do not believe in public bodies undertaking the care of cases making high payment, as this can be better done by private enterprise and without the "red tape" so dear to public authorities. This suggested limitation of municipal accommodation for private patients is clearly acknowledged by Mr. P. M. Martineau in the first report of the London County Council Asylums Committee for Claybury in 1893, when he described it as an effort of the London County Council "to provide for a class of patients above the pauper class, but who can ill afford to bear the cost of a private asylum, and who may find comparative quiet and comfort—perhaps even a touch of 'home'—in such an institution as the Claybury mansion house." In regard to insanity as in other diseases the neglect of ordinary hygienic rules and the failure to observe natural laws are inevitably and remorsely punished. Nature is a good friend but a bad enemy, for she never forgives a wrong, and she is again wholly selfish—perhaps, more correctly, wholly just—for she invariably decides the race to the swift and the battle to the strong. It is in the observance of a proper health code and by an adherence to temperance in all things that insanity can best be prevented. If only the evils of alcohol and venereal disease were disposed of then half the problem of insanity would disappear with them. Many suggestions on the lines of reclamation, education, and restriction have been made for fighting intemperance, but hitherto they have not been distinguished for their wisdom or practical statesmanship. As a medical association we should carefully consider in what way we can best assist towards restricting drink and drunkenness and I for one welcome the attempts of the National Temperance Legislation League (of which Viscount Peel is the President and Sir Thomas Whittaker the chairman of executive) to bring its views before the country and the legislature with the object of promoting sobriety in such ways as local conditions and public opinion may render possible.

We accept the statement that society is bound to provide for and to support its own languishing sick and feeble, but when 1 in every 285 persons of the population is an inmate of a lunatic asylum, when 1 in every 157 during the year 1905 has undergone a term of imprisonment for offences against the law, when 1 in every 100 children of elementary school age is so mentally or physically defective as to require special educational facilities, and further, when 1 in every 36 persons in England and Wales and 1 in every 31 in London is a pauper, it is surely time that some stir were made. The whole of this so-called "defective class" have a right to be *protected* against themselves and the control which they lack should be supplied to them from without; at the same time society has a right to be protected from the transmission of their defective qualities to future generations. I have no sympathy with the crude and barbarous mutilations proposed by indiscreet and fanatical persons who are devoid of any quality of sympathy or patience necessary to enlightened reform.

It appears to me to be necessary to subdivide and classify the whole of the defective classes and if possible to bring them all under one great department of State, so that in youth they may be specially notified and registered, in adolescence be strictly observed, and in maturer years those of them still supervised who have not succeeded in taking their place in the community as contributors to its welfare, and in this way *they would* be *saved from a life of* crime, vice, or any of the forms of pauperism. So much may be involved in this suggestion that it may well form the basis of inquiry and investigation by another Royal Commission. I am of opinion that insanity, which of all illnesses inspires terror beyond *any other and causes a sense of* helplessness, might be lessened if the hospitals of *our* cities (whether associated with a medical school or not) were to initiate outpatient departments where *patients could apply for advice* and submit to treatment for mental symptoms without loss of *liberty. Where this experiment has been tried* it has proved *most satisfactory.* Moreover, our public asylums, built and *supported by the ratepayers, should give them some relief and benefit in return. They* should be the centres for disseminating, *through their medical officers* and nurses as missioners, a *health conscience* and a creed which should reform the districts they serve. Each of our asylums should be a centre for *clinical* instruction. It should be a school where any qualified medical practitioner could refresh his knowledge ot the subject of insanity in all its bearings and where the medical staff should give advice to any applicant *suffering from premonitory symptoms* of incipient insanity, and power should be given by law to take such cases in for treatment if necessary as *voluntary boarders.* An asylum should be the place where the principles of Eugenics should be widely disseminated, for surely it is wiser and better to make every effort to arrest insanity before it has reached the stage of certificates than to wait until it has been legally established. Every *facility should be given by public bodies* for students and medical men to receive full and adequate clinical and systematic instruction in insanity and there should be a diploma in mental diseases granted by the Royal Colleges of Physicians and Surgeons which should be a qualification necessary before any *medical* officer *can* receive the higher appointments in public asylums, just as the *diploma of* D.P.H. *is* necessary *for medical officers* of health. The University of London has already taken a step in this direction by the recognition of mental diseases as a special subject for the M.D. examination and the further question of a diploma is worthy the attention of the University authorities.

[Dr. Jones here referred to the teaching of hygiene and temperance in elementary schools, to the after-care and boarding-out of the insane, and to the probable influence of old-age pensions in *reducing* the number *of* aged *persons in* asylums. He continued as follows :]

May I ask in conclusion what our great national association is doing and has done in the direction of mitigating insanity. Our association has risen, owing to the vigilance and faithful care of our treasurer, to be, so far as financial position and annual income are concerned, the second of the medical societies of this country. Founded in 1841 with a membership of 44, it can now boast of a roll of over 700 qualified *medical men and women* interested *in the improved* treatment of the insane. Such membership must be a bond of union to all *asylum workers and this bond is* greatly strengthened by our representative journal, so ably conducted under the experienced editorship of Dr. H. Rayner, Dr. Conolly Norman, Dr. A. R. Urquhart, and Dr. J. Chambers. With the view of encouraging investigation and research *our* society continues to hold an examination in mental medicine for qualified medical practitioners engaged *in the asylum services* and *a certificate* is granted by the association as a mark of proficiency, and I consider this encouragement and *the continuance* of this examination to be imperative upon us until such time as the universities and conjoint medical *colleges* take the matter up. This year six candidates have been successful in obtaining this certificate. A medal with an honorarium of ten guineas is also *offered annually* for an essay by any assistant medical officer upon a subject connected with the clinical study of mental diseases and *two essays* of remarkably ability have recently been presented, one *dealing* with the special pathology of insanity, the other dealing with the incidence of tubercle. Further, a prize of £30 and a gold medal are also open to assistant medical officers as an incentive *to the study* of insanity and both are this year awarded. *The* improvement of nursing in our asylums and mental hospitals has always been an object of *much solicitude* and of considerable interest to the *council* of our association. Didactic instruction in the form of lectures to the staff by the asylum medical officers, *according to* a syllabus laid down by the *association, has become the almost invariable* rule in asylums throughout the three kingdoms as well as those of some of our *colonies. The period of training* for the certificate of the association *for proficiency in* mental nursing now extends *to* three years and such training enables the holders to obtain *better executive positions in various institutions* as well as in private nursing, and by ensuring better prospects encourages *a more* ambitious and a better class of nurses. The records kept by our energetic and methodical registrar, Dr. *Alfred Miller*, show that there are at present no *less* than *7555* persons—*3549 men and 4006* women—who have obtained the certificate for proficiency in mental nursing, and *I think the least* we can expect *for* those who *thus* devote themselves to duties which, were they not essentially Christian *in the highest sense* of the term, would be positively repellent *is that with regard to their* later days they should at least be placed in such ease and comfort as to old-age provision as the ordinary policeman. More we do not ask, and I am happy to think public opinion is now maturing towards the view that they deserve as much.

During the past year we have had a special committee, under the *chairmanship of Dr. R. Percy Smith,* to consider the classification of insanity. This committee in the light of our present knowledge of psychology, pathology, and symptomatology has discussed the matter very fully and has endeavoured *intelligently* and practically to subdivide the whole of mental diseases, to rearrange them, and thereupon to suggest a nomenclature which, if not final, is at any rate a workable scheme *in* harmony with the united opinions of members of the committee and based upon psychological and pathological *knowledge as they fit in with the* various symptoms presented. This year also witnessed the final presentation of a scheme of statistical tables, which to *be of* any use for the collation of our knowledge and for general information in respect to insanity requires the loyal coöperation of every member of our association. The committee, with Dr. D. Yellowlees as chairman, deserves the very grateful *thanks of* the whole association for the *years of* elaborate and consistent devotion to this task.

In conclusion, I would suggest that an annual lectureship be endowed by our prosperous association dealing with insanity in its sociological aspect, for the more we work into these side issues the more do we *feel that the life of* intellect, of emotion, of action, of thought, and even of pleasure have effects which command our earnest attention. The whole question of insanity demonstrates what a great *thing life is,* and that there is *no* aspect of it unworthy *of* study or destitute of interest.

A Lecture

ON

EPIDEMIC CEREBRO-SPINAL FEVER, WITH ILLUSTRATIVE CASES.

Delivered in the Glasgow Royal Infirmary

BY JOHN LINDSAY STEVEN, M.D. GLASG.,
PHYSICIAN AND LECTURER ON CLINICAL MEDICINE, GLASGOW ROYAL INFIRMARY; HONORARY LIBRARIAN, FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW; AND REPRESENTATIVE OF THE FACULTY ON THE GENERAL MEDICAL COUNCIL.

GENTLEMEN,—*During the past* few months a number of cases presenting the features of epidemic cerebro spinal fever or meningitis have occurred in *Glasgow. A memorandum on the* subject for the *consideration* of the health *committee has been prepared by* Dr. A. K. Chalmers, medical officer of health of the city. Extracts *from* this *memorandum* were published in the daily papers on June 23rd last giving a *statement* of the facts as regards the number of cases, ages of the patients attacked, &c., so far as then known to the health authorities.[1] From March 10th, 1906, till that date *information* had been obtained of *44 cases, 32 being under* the age of 15 years and 30 of the patients having died. On June 7th, when I had an interview with Dr. Chalmers concerning the patient who died in Ward 12, and whose case during our ward visits I demonstrated to you as a characteristic example of epidemic cerebro-spinal meningitis, he courteously informed me that on that day they had information of 29 cases of which 20 had terminated fatally; Weichselbaum's diplococcus intracellularis had been demonstrated in eight or nine of them; and of five post-mortem examinations which had been made revealed the anatomical changes of cerebro-spinal meningitis, although only four yielded the diplococcus from the meningeal exudate, the fifth having been associated with the staphylococcus and being clearly of septic origin.

---

[1] *This statement* has also been published in THE LANCET and British Medical Journal of June 30th, 1906. In THE LANCET of the same date a paper dealing with the first ten cases of the epidemic, by Dr. William Wright and Dr. W. Archibald, assistant medical officers of health of Glasgow, was published.

I think the credit of first directing attention to the probable presence of a disease resembling epidemic cerebro-spinal meningitis among the children of the city must be given to Dr. J. W. Anderson of Dennistoun who during 1905 asked me to see one of his cases in an infant, about a year old, in whom the retraction of the head and Kernig's sign were well marked but in whom no bacteriological examination was made. At Dr. Anderson's request I drew up a short report stating my opinion that the child was suffering from cerebro-spinal meningitis, which he submitted to Dr. Chalmers. In his memorandum Dr. Chalmers writes as follows: "During 1905 I had, through the courtesy of Dr. Wallace Anderson of Dennistoun, repeated opportunity of seeing with him several isolated cases of meningitis of a type which he considers to have been present since 1901. No suggestion of grouping, however, occurred nor were there any in which the organism was recovered until the following incidents arrested attention." Dr. Chalmers then goes on to refer in detail to the cases which occurred on and after March 10th, 1906, in many of which Weichselbaum's diplococcus was recovered. Dr. C. Workman informs me that in the post-mortem journals of the Glasgow Royal Infirmary since that date five cases have been recorded all affecting adults: in three cases, Weichselbaum's diplococcus; in one case, the pneumococcus; and in one case, no report. These are the chief facts that have been elicited by the health authorities of the city, and they are of such importance as fully to justify the most scrupulous investigation of all cases of meningitis both by the municipality and by individual medical men.[1]

During the present outbreak of the disease in the city I have had the opportunity of seeing three characteristic cases, one of which you have also watched in the wards and followed to the post-mortem room. The other two I saw in private. It is fitting, therefore, that at this the last meeting of the class for the present summer session I should describe to you the clinical features of these three cases in the course of a formal lecture on this interesting and fatal disease.

CASE 1.—A man, aged 21 years, married, a labourer, was admitted to Ward 12 on May 30th, 1906, at 7 P.M. on account of vomiting, headache, great restlessness, and unconsciousness. Since childhood, with the exception of whooping-cough, measles, and scarlet fever, he had no illness until eight months before admission, when he was away from his work for a week on account of an attack of "black bile," accompanied by vomiting but without unconsciousness. On the evening of May 29th he was suddenly seized with severe sickness and vomiting which lasted continuously for five hours. There was also some diarrhœa and he complained of tenderness and pain in the region of the stomach. The colour of the vomited matter was green at first, but afterwards became black. This attack came on suddenly after he had taken his supper consisting of tea and sausages. Before having his supper he had been in a friend's house, where he drank some whisky out of a bottle. The violence of his illness suggested to his friends that the contents of the bottle might not have been whisky but something poisonous; on inquiry, however, it was found that the bottle had contained whisky. On the morning of the 30th headache was so intense that he could not get out of bed. At 2 P.M. on that day he became unconscious and extremely restless, moving his arms and legs about in an irregular fashion. At 7 P.M. in this condition he was admitted to Ward 12. His mother stated that he had been out of work for about a fortnight, but had not been particularly depressed on that account. He lived at home in a room and kitchen house with his father and mother, both of whom were healthy; his brothers and sisters numbered seven and all were in good health; two others had died in infancy, one from croup, the other from "inflammation of the brain." He was married and had one child, who had died in the Hospital for Sick Children from tuberculous meningitis as ascertained by post-mortem examination there.

On admission to the ward the patient was quite unconscious and extremely restless, so that it was necessary to procure a night-watchman to prevent his falling out of bed. The face was flushed and the tongue was coated with a white fur; the breath had a peculiar offensive odour. There were no herpes and no cough or spit. The pupils were equal and medium and reacted to light. No paralysis was anywhere noted. He frequently passed his hand over the abdomen, so as to suggest that he might be suffering pain in that region, but a careful examination of the abdominal walls, the inguinal rings, and the rectum revealed nothing abnormal. The stomach was washed out; the contents were greenish in colour and contained no free hydrochloric acid. The urine removed by catheter had the following characters: colour, amber; reaction, acid; albumin, present; sugar, present; chlorides, diminished; acetone and diacetic acid, absent. There was no œdema of any part of the limbs or trunk. Kernig's sign was absent. The pulse was 78, the temperature was 99° F., and the respirations were 28. Examination of the circulatory and respiratory systems was difficult on account of the restlessness and struggling, but so far as it could be carried out it pointed to a healthy state of the heart and lungs. Such is the clinical history as recorded by my resident assistant, Dr. McEwan; the subsequent notes of the case were dictated by myself in your presence when we examined him together.

On May 31st, in the morning, the patient was still unconscious and extremely restless, constantly moving the limbs and turning the body from side to side. The unconsciousness was not very deep, as any examination of the patient increased the restlessness. A distinct rigidity of the nuchal muscles was observed. This, indeed, was so great that he could be raised from the bed by the hand placed beneath the occiput, the spine being kept quite rigid during the whole time. Occasionally a slight tendency to opisthotonos was noted. The attempt to raise him in this way also caused him to cry out a little as if he were in pain or discomfort, but he never regained consciousness. The abdomen was markedly retracted and the tache cérébrale was well marked. The skin was of a somewhat oily character; here and there blotches and pimples were noticed but no definite specific rash could be detected. The pulse was of small volume, regular in force and rhythm, and numbered about 100. The respirations were irregular, there being an intermission of varying duration every third or fifth breath. The respirations numbered about 20, although they were somewhat difficult to count owing to the intermissions. The temperature had gone up from 99° on admission to 101° at 1 o'clock and 102° at 8 o'clock this morning. Occasionally a slight twitching of the right angle of the mouth and of the right eyelid was observed. It was impossible to test for Kernig's sign on account of the extreme restlessness. The patient was able to swallow when fluid was placed in the mouth, but the lower jaw was rigid. There had been no vomiting and no diarrhœa since admission. The restless movements sometimes ceased for a few minutes, during which the patient seemed to be asleep. At times during the restless periods he uttered a low moan as if he were in pain. No wound could be discovered on the body and the idea of the disease being tetanus was dismissed. The rigidity of the neck, the unconsciousness, the extreme muscular restlessness, the irregularity of the respirations, and the history of onset with violent vomiting and purging suggesting irritant poisoning on the whole indicated the possibility of cerebro-spinal meningitis. On June 1st the patient was much less restless but greatly more comatose than at the ward visit on the previous day. The pupils were now somewhat dilated and did not respond to light. The eyelids were sealed by a purulent exudation. During the night and the next morning Cheyne-Stokes breathing of a characteristic kind had been present, the respiratory period lasting from seven to ten seconds, the period of apnœa from three to five. The respirations were stertorous. The pulse was of small volume and low tension, numbering 140. The temperature at the time of the note was 103°, having been 102° at 8 o'clock the previous night. No definite petechial rash could be made out, but there was a slight livid mottling of the dorsa of the feet, a similar condition being noted on the upper part of the front of the chest. A distinct paralysis of the left side of the face and a paresis of the left arm were noted this morning. Retraction of the head was still marked, and any attempt to bring it forward met with the strenuous opposition of the patient. He occasionally placed his hand behind his neck as if holding it for the relief of pain. He swallowed a little milk during the night. The bladder had been quite incontinent, but the bowels had not moved since admission. Examination of the fundi showed slight congestion of the optic discs. After the ward visit on May 31st lumbar puncture was performed and two drachms of slightly blood-stained cerebro-spinal fluid were withdrawn, the admixture of blood being obviously accidental. Part of the fluid was sent to the municipal bacteriological department, and part was examined by Dr. McEwan. On standing a slightly red-coloured faint flocculent deposit settled in the tube, leaving the supernatant fluid perfectly clear. On staining films from the deposit with 10 per cent. fuchsin solution it was found to consist mainly of polymorphic leucocytes in the interior of many of which characteristic diplococci, varying in number from four or five to 20, were beautifully seen. The examination of the cerebro spinal fluid thus confirmed the diagnosis already arrived at of epidemic cerebro-spinal fever. Dr. R. M. Buchanan of the municipal laboratory also reported that in the specimen sent to him he had detected the diplococcus intracellularis meningitidis of Weichselbaum. The patient sank and died in the course of the evening of June 1st, the temperature having dropped shortly before death to 100°. He had been ill barely three days.

---

[1] On June [illegible], the day after this lecture was delivered, Dr. Wright, senior assistant medical officer of health of Glasgow, informed me that the number of cases was [illegible]; that [illegible] had been subjected to post-mortem examination and [illegible] chiefly associated with Weichselbaum's diplococcus.

Necropsy.—A post-mortem examination was made on June 4th by Dr. Workman, pathologist to the infirmary, whose report is as follows: "External appearances.—A well-developed and well-nourished body. Post-mortem rigidity is pronounced. On removing the calvarium and reflecting the dura an extensive fibrino-purulent meningitis of the brain is observed, most advanced over the right hemisphere where the effusion is very thick and yellow. The disease does not seem so advanced at the base, but the membranes there are very opaque. The effusion is great between the lobes of the cerebellum behind. On removing the spinal cord the inflammation and effusion are found most pronounced over the lower dorsal and lumbar regions. The organs of the thorax and abdomen are found to present remarkably healthy appearances. The spleen is not enlarged, but there is perhaps a very slight cloudy swelling of the liver. Smears from the purulent exudation of the meninges on being stained show numerous diplococci of Weichselbaum, and the same organisms are found by Mr. J. A. Campbell, assistant bacteriologist to the infirmary, on culture. Weights of organs: heart, 12 ounces; right lung, 28 ounces; left lung, 22 ounces; liver, 58 ounces; spleen, 4 ounces; kidneys together, 12 ounces."

The post-mortem examination of this case fully verified the diagnosis at which we had arrived during life. I shall now shortly describe to you two other characteristic fatal cases occurring in the same family which I saw in consultation with Dr. Joseph N. Glaister on the evening of April 17th last. I shall simply read to you the notes which I made at the bedside and afterwards transcribed into my case-book immediately on returning home.

CASE 2.—Alice ——, aged three years, was well enough till Saturday afternoon, April 14th, when in the early evening, about 5 o'clock, she was observed to be heavy and dull. She then went out for a walk with her parents but had to be carried home and put to bed; since then she had been quite prostrate. All the Saturday night she was restless and perspired very much. Her mother poulticed her, thinking she had caught cold. Severe vomiting began on Sunday the 15th, at 2 o'clock P.M., and continued till Monday night. There was no diarrhœa but one good, though constipated, motion had been obtained on the 15th as the result of castor oil. On the evening of the 16th restlessness became more marked and retraction of the head was first noticed. When I saw her on the 17th the retraction of the head was very distinct and the nuchal muscles were very rigid. The child was still very restless, rolling about in her nurse's lap, and unconscious, or very lethargic. The pupils were dilated but responded slightly to light; slight squinting was now observed for the first time. The pulse was 120 and regular; the temperature was 101° F.; the respirations were 26 and occasionally of Cheyne-Stokes type. A few doubtful spots were observed on the trunk but their nature was difficult to determine in the gaslight. The tongue was dry and covered with a thick white fur.

The child, after improving somewhat, relapsed and died on May 5th, after 22 days' illness. On the 7th I was present along with Dr. Glaister, Professor J. Glaister, Dr. Chalmers, and Dr. J. Browne of Belvidere at the post-mortem examination, which was performed by Dr. Buchanan. The appearances revealed were typical of cerebro-spinal meningitis. The convolutions of the convexity were flattened and dry and here and there a little yellow exudate was observed in the sulci. The fluid in the ventricles was excessive in amount and presented an opaque grey appearance. A thick layer of pale yellow exudation enveloped the pons Varolii and upper part of the medulla oblongata, extending backwards on either side over the lower surface of the cerebellum. On the posterior surface of the dorsal region of the spinal cord there was a thick layer of yellow fibrinous exudation. Cultures were made by Dr. Buchanan from the exudate and from the cerebro-spinal fluid with, I understand, positive results.

CASE 3.—Maggie ——, aged eight years, sister of the foregoing patient, remained quite well till about 2 or 3 o'clock P.M. on Sunday, April 15th, the day after her sister turned ill when she sat on the fender and shivered. She was at once put to bed, and at 5 P.M. she seemed a little better and went to sleep till about 7 P.M., after which she became very restless and remained so all night. On Monday forenoon severe vomiting began, continuing till shortly before my visit on the evening of the 17th. I saw the vomited matter at that time and it had a black tarry appearance. At this time also there were very marked retraction of the head and extreme restlessness. She was extremely lethargic and the temperature was 103° F. The pupils were wide and responded to light. A number of round red spots were noted on the front of the chest and abdomen. The bowels had been moved by medicine and the motions were also said to have been somewhat tarry in appearance. This child died about four days later. No post-mortem examination was made, but Dr. Buchanan obtained Weichselbaum's diplococcus intracellularis from the opaque cerebro-spinal fluid obtained after death by lumbar puncture.

The violence of the initial vomiting in these two cases, just as in the case we observed together in Ward 12, raised at first the question of the possibility of irritant poisoning as the cause of the symptoms. After careful inquiry, however, Dr. Glaister and myself agreed that this hypothesis might be set entirely aside and that the disease from which the little patients were suffering was acute cerebro-spinal meningitis. We further agreed that the cases should be reported to the medical officer of health. This was done by Dr. Glaister next morning and with reference to the presence of a rash in these cases Dr. Chalmers, who afterwards saw the patients with Dr. Glaister, writes in his memorandum as follows: "In the children forming Group 2 above noted a limited number of spots were present on the skin from the third day of their illness. These were few in number, petechial in character, and irregularly distributed. In one child they were present on the abdomen and ankle, in the other on the neck and upper part of the chest and on the inner aspect of the thigh and ankles. They were more pronounced than a typhus rash and much more limited in distribution."[3]

The epidemiological history of cerebro-spinal fever has been written in numerous monographs and reports during the nineteenth century and it is impossible to enter into a detailed discussion of this interesting subject now; it will be sufficient if I refer you to the chief sources of information on this point. Perhaps the most complete of the earlier accounts is that of Hirsch, contained in the third volume of his "Historical and Geographical Pathology," as translated into English by the New Sydenham Society. A good historical outline is also contained in Edward W. Collins's "Report upon Epidemic Cerebro-spinal Meningitis" published in the *Dublin Quarterly Journal of Medical Science*, vol. xlvi., 1868, p. 170. Among more recent contributions undoubtedly the best is the Report on Epidemic Cerebro-spinal Meningitis prepared for the Massachusetts State Board of Health by Councilman, Mallory, and Wright in 1898 dealing with the outbreak in Boston in 1896-97, during which 111 cases were minutely investigated, clinically, pathologically, and bacteriologically. Hirsch divides the epidemic prevalence of the disease in the nineteenth century into four periods: (1) 1805–30, the outbreaks being chiefly in the United States; (2) 1837–50, chiefly in France and Algiers; (3) 1855–75, chiefly in Germany; and (4) 1875 till the present time.

---

[3] In THE LANCET of July 7th, 1906, p. 47, Dr. Chalmers has added to this statement by saying that since it was published he has seen a case in a child in which "the features of a typhus rash were exactly reproduced within limited areas of the skin" on the fourth day from the onset.

Up to 1868 the appearance of the disease in Great Britain was, according to Collins, confined chiefly to Ireland where in the majority of the workhouses of the country it first occurred in 1846; a remarkably fatal outbreak also began in 1866 and lasted till the date of his report 1868. Writing in that year Collins states: "Cerebro-spinal meningitis has never become epidemic in England. Indeed, so rarely has it been observed there that the fact of its occurrence in that country might almost be passed over in silence." Sporadic cases had, however, been reported from 1807 onwards. "If," he continues, "we now glance at the diffusion of cerebro-spinal meningitis upon European soil during the present century, we find that Turkey, Greece, Belgium, Scotland, Iceland, and Russia alone, so far as our present limited information warrants such an assertion, have remained unscathed." Probably the first outbreak to be recorded in Scotland in detail was that occurring in the village of Galston in Ayrshire reported by Dr. W. Frew, now of Kilmarnock, in the *Glasgow Medical Journal*, July, 1884, p. 21. I remember being present at the meeting of the Glasgow Pathological and Clinical Society at which Dr. Frew read his paper and of seeing specimens which he had sent to Dr. Joseph Coats from his post-mortem examinations.[4] I have seen one or two other sporadic cases, but I know of no other epidemic outbreak in the West of Scotland since then.

In the Massachusetts report the authors remark that, "as a rule, none of the epidemics has shown a continuous extension," and that "the outbreaks of the disease have been seen as perfectly isolated epidemics in places which had hitherto been free from it." Many of the epidemics have not embraced more than from four to six cases, and most of the accounts concern only sporadic cases. All the epidemics have been most marked in the winter and spring and the disease attacks chiefly children and young adults. Epidemics have also been frequent in garrisons and in convict prisons, sometimes, indeed, limiting themselves to the military and sparing the civil population. One of the most striking features of the epidemiology of cerebro-spinal fever is the limited number of cases and the isolated character of many of the outbreaks. As regards the earlier accounts one wonders whether all the cases recorded were really to be regarded as examples of cerebro-spinal fever, particularly such cases as could be designated "spotted fever." Murchison and others believed that epidemic cerebro-spinal fever was but a modification of typhus fever, and although it must now be admitted that this is not so it is quite likely that cases of typhus fever were included in the statistics of earlier epidemics. By the use of the lumbar puncture we are now able to be much more accurate in diagnosis. In the epidemics which have occurred during recent years in Europe and in America the numbers of cases have been relatively large. In Silesia in the spring of 1905, 1953 cases were recorded with a death-rate of 50 per cent.; the disease had been absent from Silesia for 30 years. In New York in February, 1905, deaths to the number of 149 occurred, and a commission was appointed to devise measures of prevention; in the same city in 1872 there were recorded 990 cases with a death-rate of 77 per cent. During the first seven months of 1898 in Chicago close upon 200 cases were observed and a report on the disease was prepared by Dr. W. J. Class and published in the *Journal of the American Medical Association*, March 25th, 1899. Addressing the centennial meeting of the Medical and Chirurgical Faculty of Maryland in April, 1899, Professor W. Osler called the affection an "American disease," and referred to the value of lumbar puncture in establishing the diagnosis.

Such facts as I have mentioned, and they might be multiplied indefinitely, fully establish the epidemic character of the disease. But there still remain for consideration the sporadic cases. These, though perhaps rare in occurrence, are apparently always with us. Are they of the same nature as the epidemic disease? I think undoubtedly that some of them are. In a number of sporadic cases an organism similar to Weichselbaum's diplococcus has been discovered and in others the pneumococcus has been present. In London there has long been recognised a form of meningitis which has been designated posterior basic meningitis or cervical opisthotonos, an affection which has been carefully investigated by Still and Hildesheim.[5] In some of these an organism closely resembling the diplococcus of Weichselbaum has been discovered. It is perhaps, however, as yet impossible to say whether the sporadic is essentially the same as the epidemic disease, but so far as I can judge from the evidence at present before me I think they are. If this be so, then we have to recognise the fact that cerebro-spinal fever may not only be epidemic but also endemic; that as regards its prevalence in the community it may somewhat resemble pneumonia: it may be always with us and yet liable to epidemic outbreak.

As regards the bacteriology of epidemic cerebro-spinal fever there is still difference of opinion as to whether it is caused by one specific organism or not. There can be no doubt that cerebro-spinal meningitis is capable of being produced by several micro-organisms—the pneumococcus, Weichselbaum's diplococcus intracellularis meningitidis, the tubercle bacillus, the streptococcus, &c. In many of the cases due to other organisms than the diplococcus intracellularis the meningitis is secondary and so may be excluded from consideration in the investigation of the etiology of epidemic cerebro-spinal fever. Jaeger, Heubner, and Councilman, Mallory, and Wright incline to the view that the epidemic form of cerebro-spinal meningitis is caused by Weichselbaum's diplococcus alone, whilst Netter, who has written largely and well on the subject, does "not in any way accept this view," and he regards it as "even possible that the diplococcus intracellularis may be a degenerated form of the pneumococcus."[6] In this connexion it may be interesting to quote the conclusions of G. Canby Robinson, of the Ayer Clinical Laboratory, Philadelphia, who has made one of the most recent investigations into the bacteriology of epidemic cerebro-spinal meningitis.[7] "In a study of 15 cases of epidemic cerebro-spinal meningitis the organism isolated from the spinal fluid, circulating blood, pus from the conjunctiva, and from the central nervous system at autopsy, agrees in all respects to the diplococcus intracellularis meningitidis of Weichselbaum. It was isolated in pure culture from the spinal fluid of the 14 cases in which lumbar puncture was performed and is to be considered the causal agent in all the cases." It is therefore, perhaps, impossible at present to be absolutely certain that the diplococcus intracellularis is the specific organism of epidemic cerebro-spinal fever, but notwithstanding the able ratiocination of Netter I am inclined to think that the further investigation, which is still necessary, will prove that it is so. Certainly from the clinical point of view, and so far as the bedside phenomena of the cases here recorded go, there seems to me to be little doubt that epidemic cerebro-spinal fever is as specific as typhus fever.

Netter is a firm believer in the contagious nature of epidemic cerebro-spinal meningitis, but points out that the earlier observers of the French epidemics had little belief in it. It is admitted, however, that "the degree of contagiousness is less marked than that of most of the other infectious diseases." In this respect it may be said to resemble tuberculosis or enteric fever as regards its contagious quality. As regards the mode of contagion, some believe that the poison may be conveyed in the excretions from the nose. Quite recently also Canby Robinson reports that he has isolated the diplococcus intracellularis meningitidis from the pus of the purulent conjunctivitis which sometimes complicates epidemic cerebro-spinal fever, as it did in our first case. A number of observers believe that the path of infection may be by way of the lymph spaces of Axel Key passing "through the fronto-ethmoid foramen or the cribriform plate of the ethmoid bone." While admitting the possibility of direct nasal infection, Netter believes "that the pathogenic agents most frequently reach the meninges by way of the blood, and that they enter this fluid from the pulmonary alveoli." Such observations teach us that the excretions from the nasal cavity and from the conjunctivæ are highly dangerous, and that in the nursing of every case of cerebro-spinal meningitis careful provision should be made for their thorough disinfection. As regards the first case reported in this lecture Dr. Chalmers kindly ascertained for me the following facts which may have a bearing upon the question of contagion. The patient in Case 1 had a baby boy who died in the Sick Children's Hospital on April 21st, 1906, certified "meningitis"—tubercular (P.M.). He is said to have kissed the child after death. Further, it was found that a child, aged five years, a cousin of the patient, died on May 10th, 1906, certified as "probably meningitis." He visited this child's house and is said to have also kissed the child after death. Of course too much cannot be made of this in support of the doctrine of contagion but the circumstances are at least of interest in connexion with the patient's own illness and death, and they certainly indicate that it may be dangerous for the parents and relatives of children suffering from meningitis to kiss them.

[7] Bulletin of the Ayer Clinical Laboratory of the Pennsylvania Hospital, Philadelphia, Pa., No. 3, June, 1906, p. 27.

The diagnosis of cerebro-spinal fever while the disease is prevailing in epidemic form should not be difficult, although it must be admitted that sporadic cases from the likelihood of their being confused with the ordinary meningitis of infancy and childhood may give some trouble. Cases such as those described in this lecture present no great difficulty in diagnosis and would not, I think, do so even if they had occurred as sporadic cases. The onset as sudden as that of pneumonia, the rigor, the violent initial vomiting raising sometimes the suspicion of irritant poisoning, the headache of excruciating severity, the restlessness and rapid onset of unconsciousness, the retraction of the head and manifestations of pain on attempts to bring it forward, the occasional presence of a petechial rash, and Kernig's sign make up a clinical picture the significance of which cannot easily be mistaken. In *foudroyant* cases the passage of the patient in the course of a few hours into a state of coma and extreme danger is one of the most striking phenomena of the disease. Yet it is possible that symptoms very similar to these and due to other causes altogether may sometimes be met with and lead to a diagnosis of cerebro-spinal meningitis when that disease is not present. Such a case occurred in Ward 7 during the past winter. I made a diagnosis of cerebro-spinal meningitis, in which my colleague Dr. George S. Middleton agreed. The symptoms had caused my resident to think of typhus fever; I saw the patient only once and he died within 24 hours of admission, the illness having lasted only three days. The post-mortem examination proved that the case was one of fæcal impaction and poisoning and that the brain and spinal cord presented healthy appearances. The following are the notes of the case.

CASE 4. *Fæcal poisoning erroneously diagnosed as cerebro-spinal meningitis.*—A man, aged 20 years, was admitted on Dec. 31st, 1905, and died on Jan. 1st, 1906. He had been suffering from an illness of three days' duration. The history of the illness cannot be obtained at present but the following details are supplied by Dr. S. C. Cowan of Kirkintilloch who had sent in the patient. "Illness began three days ago, when giddiness and weakness of the legs were complained of. Ankle clonus is very marked and the other reflexes are exaggerated. Temperature has been above normal. Pulse 120. Bowels have been freely moved. Intense thirst has been present. Urine normal. Tongue has been dry from onset." His condition on Dec. 31st at 7.30 P.M. was as follows. The temperature was 97° F., the pulse was 102, and the respirations were 30. The patient lay on his right side and was practically unconscious. The breathing was very laboured, marked muscular effort being used to get each breath in. There was movement of the jaw, nose, and throat with each respiration. The face was flushed and the ears were very livid. The pupils were moderately contracted but became smaller under a strong light. In watching them they were seen to contract slightly with each respiration. The conjunctivæ were clear The tongue was exceedingly dry. The general condition was that of a strongly-built, rather spare man. The extremities were very cold. The skin was in a dirty condition on admission; on inspection afterwards there was seen a mottled appearance consisting of small patches of brownish pigmentation to be found on all parts of the body but not the face. The colour was very faint on the chest, abdomen, and back, and was more marked on the limbs. It was very specially distinct on the dorsa of the feet where the colour was a distinct brown. Along with this mottling there were definite spots, small red papules, slightly elevated, and disappearing on pressure. These were very scattered, being most marked on the forearms but also present on the chest, the abdomen, the back, and the legs, and there were one or two on the brow. Owing to the restlessness of the patient a detailed examination of the various viscera was not possible and it was necessary to provide a male nurse to watch at his bedside. There was pulsation in the third and fourth spaces of the heart, the apex beat seemed to be in the fourth, three inches to the left. The cardiac dulness was certainly not enlarged. The sounds were pure. The lungs were resonant all over and the respiratory murmur was vesicular and free from adventitious sounds. The abdomen was tympanitic and well formed. There was no enlargement of the liver or the spleen. As regards the nervous system, the knee and Achilles tendon jerks were exaggerated, as were also the tendon reflexes in the arms. Ankle clonus was obtained by the medical man who sent the patient in but was not now found. No plantar reflex was obtained. Sensation could not be tested. On ophthalmoscopic examination of the right eye the fundus was found to be normal. No urine had been passed since admission (12 noon). The rectal temperature taken afterwards had not risen above 95°. On Jan. 1st the patient continued in the same collapsed condition all day. The lividity of the whole body became more marked and the temperature would not rise at all in the thermometer, even when taken in the rectum. At 6 P.M. the breathing became worse and the patient gradually sank. There was at no time retraction of the neck or opisthotonos. The body, however, was somewhat rigid, but in a flexed state. Restlessness was a marked feature throughout but the patient never regained consciousness. The conjunctivæ remained clear throughout. No urine was passed. At the visit this morning I considered the blue mottling a "*tâche bleuâtre*," and the case was diagnosed as probably cerebro-spinal meningitis. This opinion was also expressed by Dr. Middleton.

Necropsy.—The following are the notes of the post-mortem examination: "Ptomaine poisoning from extensive fæcal accumulation in ascending and transverse colon. Descending colon and rectum empty. The weights of the various organs are: heart, 9½ ounces; right lung, 19 ounces; left lung, 13½ ounces; liver, 56 ounces; spleen, 2½ ounces; and kidneys, each, 4 ounces. The body was cyanosed and covered with a macular livid eruption, spots varying in size, mostly large. Death was thought to be due to cerebro-spinal meningitis. The heart was small and the pulmonary valves were competent and healthy. The mitral and tricuspid valves were healthy and of normal size. The lungs were emphysematous and congested. The spleen was small. The liver was fatty and congested. The kidney capsule was adherent in places. The pyramidal area was relatively congested. The stomach showed areas of ecchymosis. The intestines were generally congested. There was no enlargement of Peyer's patches. The cæcum was much distended and full of fæces. The whole ascending colon was distended with firm fæces. In the transverse colon were masses of fæces of the size of a walnut. The descending colon was empty. An intussusception was found in the small intestine, probably *post mortem*. The mucous membrane of the cæcum was greatly thinned and congested and in a few places was sloughing. There were patches of great congestion over the large intestine. There were no exudate at the base of the brain and no increase of fluid in the lateral ventricles; it presented a very healthy character. The spinal cord presented no exudation and was apparently healthy."

I have thought it right to record this error of diagnosis as it proves that other toxæmic conditions may give rise to symptoms not unlike those of cerebro-spinal meningitis but which would not be likely to give rise to error if the disease were known to be epidemic at the time. That this is not the only error of the kind that has been made is proved by a case shortly recorded in THE LANCET.[5] During an outbreak of epidemic cerebro-spinal fever in Egypt one case was diagnosed by several medical men as of this nature and arrangements were being made to perform lumbar puncture when the patient passed 36 ascarides lumbricoides, after which he rapidly got well.

The diagnosis of epidemic cerebro-spinal meningitis from tuberculous meningitis in the case of young infants may cause considerable difficulty; in older children the difficulty should not be so great. In the latter affection the gradual onset, the less severe gastric symptoms, the somewhat slow evolution into a critical condition, the late development of delirium and coma, and the usual absence of retraction of the head and of Kernig's sign should help us in our efforts at diagnosis. But whenever there is a doubt the lumbar puncture should be resorted to. It is quite possible that the posterior basic meningitis or cervical opisthotonos of Great Ormond-street, of which half the cases occur in infants under one year, may possibly yet turn out to be examples of sporadic epidemic cerebro-spinal meningitis, although on the whole Hildesheim inclines to the view that they are not.

---

[5] THE LANCET, May [illegible] 1906, p. 700.

As regards prognosis, I may only add that from 30 to 50 per cent. of cases of epidemic cerebro-spinal meningitis may be recovered from, often with some nervous, functional, or paralytic defect left behind. The duration of the disease may vary "from two days up to 74 days," six and a half days for acute and 28½ days for chronic cases being perhaps an accurate average.[9] The same writers further state that "we believe that all infections of the meninges other than the diplococcus intracellularis are fatal," adding, however, that this belief must be confirmed by "examination of the exudation obtained during life by spinal puncture."[10] With this belief I am in perfect agreement, especially as regards tuberculous meningitis, and the rare cases which in practice I have seen of recovery from apparently tuberculous meningitis have now to me assumed a new aspect.

In conclusion as the result of my study of this interesting disease, specially interesting to us in Glasgow at the present time, I may venture to formulate the following propositions:—(1) That sporadic epidemic cerebro-spinal meningitis or fever is probably more frequent in our midst than we have hitherto supposed; (2) that epidemic cerebro-spinal fever is to be regarded as a specific disease and that it is in all probability caused by the diplococcus intracellularis meningitidis of Weichselbaum; (3) that in many cases the diagnosis can only be rendered certain by lumbar puncture; and (4) that all personal contact with the sick of such a nature as to render possible contamination by the excretions from the nose or the conjunctivæ should be strictly avoided and that all such discharges should be thoroughly disinfected.

THE SUBMUCOUS (OR WINDOW) RESECTION OPERATION FOR CORRECTION OF DEFLECTIONS OF THE NASAL SEPTUM.

By E. FURNISS POTTER, M.D.,
SURGEON TO THE LONDON THROAT HOSPITAL.

THE advent of the "fenster" resection or "window" operation may be said to have revolutionised the treatment of deviations and other deformities of the nasal septum. Among other deformities may be mentioned the projections known as spurs or crests. The practice of removing these obstructions by sawing them off has practically been superseded by the window operation. The skeletonising of the cartilaginous and bony septum, which is an essential part of the submucous resection, allows of a much more accurate estimate of the nature of the deformity and shows that what were formerly regarded as ledge-like outgrowths of bone or cartilage, or both, are in reality but the thickened angular summits of septal deflections. This demonstrates clearly the reason why the results of attempts to saw off the obstructing "spur" were frequently so disappointing, as, for instance, on examining the piece thus removed the greater part of it would be found to consist of mucous membrane with only a small shaving of bone or cartilage, and consequently the patency of the naris would not be materially increased; on the other hand, if the operator were determined to be thorough a considerable perforation would result, the angle of the deflection having been sawn through instead of what was apparently a solid ledge.

It would be waste of space to review in detail the various operations which have been devised and performed for the cure of nasal stenosis due to malposition and deformity of the septum, but it may be safely said that none of these could be looked upon as wholly satisfactory; for the bending operations, such as Adams's, usually failed in their object owing to the resilient cartilage returning to its faulty position, and the cutting operations, such as those of Asch or Moure, although they might relieve the stenosis, yet were apt to leave a permanent perforation of considerable size. This, though it was claimed to be no disadvantage to the patient, nevertheless could not be looked upon as an entirely satisfactory result. The "window operation" is free from both these objections: the septal deformity is permanently corrected and if due care be taken the risk of a permanent perforation is extremely small. Briefly defined, the "fenster" resection consists in making an incision or incisions on the convex side of the deviation and separating the mucous membrane from the cartilage and bone over the whole area of the deviation. A vertical cut is then made through the cartilage, taking care to avoid perforating the mucosa on the concave side. Through this slit an elevator is introduced and the mucous membrane is stripped off the concavity. The whole of the deviated portion of the septum being freed from mucous membrane is now removed, either by special knives for the purpose or with punch forceps. The flap removed from the convexity is replaced so that its inner surface comes into contact with the inner surface of the mucosa of the other side, which now, instead of being concave, hangs straight like a curtain in the middle of the nasal cavity. The two raw surfaces adhere readily and the wound in the mucous membrane is usually healed in a week or ten days.

The following are the essential details of the operation:—

Anæsthesia.—If the patient be of stable temperament and it can be ascertained that the deflection is situated quite anteriorly, involving the cartilage only, and consequently the operation can be easily and quickly completed, I prefer to operate with cocaine anæsthesia only. If two plugs of absorbent cotton-wool saturated with a solution of cocaine 20 per cent. and adrenalin $\frac{1}{10}$ per cent. be placed in contact with, and on each side of, the septum and kept in position for not less than 20 minutes, the operation can be performed without any sensation of pain, and the addition of the adrenalin renders the procedure almost bloodless. If the patient, however, be nervous and not to be relied upon for self control—moreover, if the deflection extends far back, involving bone, and the appearance is such that the operation is likely to prove long and tedious—it is advisable to have resort to a general anæsthetic. In this case it is necessary also to apply adrenalin to the area to be resected for not less than 20 minutes before beginning to operate. I am of opnion that gas and ether is the best to commence with, and after the patient is "well under" the anæsthesia should be maintained by chloroform. A light anæsthesia is sufficient—just enough to keep the patient quiet.

Position.—The recumbent position with the head slightly raised will serve well, except for the removal of the lower part of the deflection—i.e., the lower border of the vomer and the incisor crest running along the floor of the nose. For this, in order to see satisfactorily, it is necessary to have the patient sitting up. On the whole I prefer the sitting up position from the commencement. It has also this advantage, that if there be any bleeding the blood escapes anteriorly instead of flowing into the naso-pharynx, as it does in the recumbent position.

Light.—The interior of the nose can be amply illuminated by means of the rays from an ordinary focal electric lamp (32 candle-power) reflected from a head mirror. Some operators prefer a Kirstein's electric head light, but of this I have no experience. It is said to be an advantage for the operator to be independent of a fixed light for reflection, and that because the rays from a Kirstein's lamp are parallel to those entering the eye a more perfect illumination of the deeper parts of the interior of the nose is obtained.

Assistance.—It is necessary for an assistant to hold the patient's head steady and to vary its position from time to time according to the requirements of the operator. An assistant can also render aid by holding the speculum, or special retractors, which are preferred by some for keeping open the naris. I have been in the habit of using an ordinary Thudicum's speculum, of as large a size as possible, and have found that it answers the purpose perfectly well.

Incisions in mucous membrane.—It is, I think, universally agreed that it is best to commence the resection from the convex side. I have found that for the more usual deflection with a vertical and horizontal angle, an L shaped incision—as advised by Freer—(Fig. 1) best answers the requirements. The vertical limb should be made along the summit of the vertical angle of deflection, should commence high up in the septum above the deviation, and should extend to below the horizontal portion of it. The horizontal cut should be made from the base of the vertical and be carried forward along the lower border of the septum till it is well in front of the deflection. The L shaped incision has this additional advantage, that it does not correspond to the slit in the cartilage, which latter is made considerably anterior to it, and therefore when the flap is replaced it well covers what becomes the anterior border of the window, so that if in making the anterior slit in the cartilage the mucosa of the opposite side be accidentally perforated the wound will be completely overlapped by the shaped flap and a permanent perforation avoided. Other incisions may be made to suit individual circumstances and varying conditions, such as, for instance, in a purely horizontal, crest-like deflection, an incision extending along the summit, with a short vertical one anterior to the commencement of the deflection, enables a superior and inferior flap of mucous membrane to be stripped off (Fig. 2).

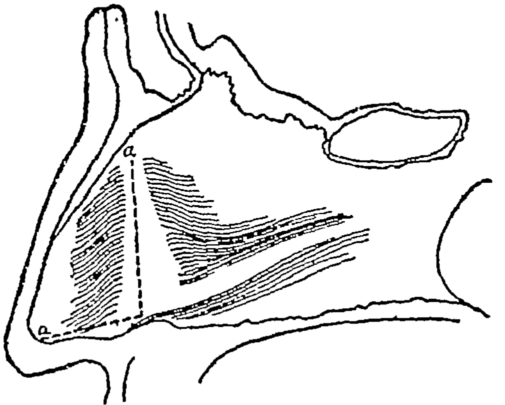
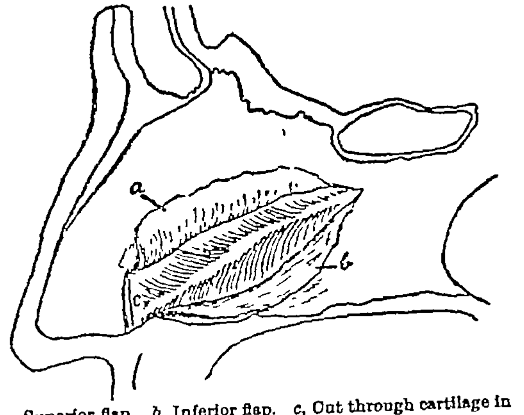
FIG. 1.



a, a, Outline of mucous membrane incision.

FIG. 2.

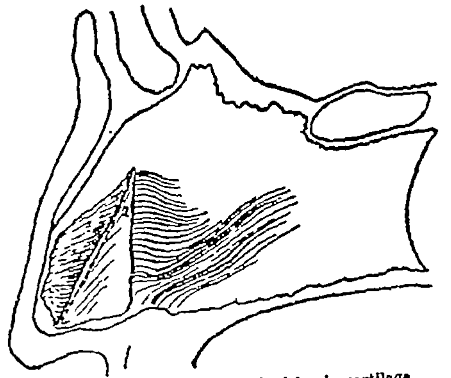


a, Superior flap. *b,* Inferior flap. *c,* Cut through cartilage in front of deflection.

In making these incisions care should be taken to avoid perforating the cartilage. This is not an unnecessary precaution, as where the cartilage is very thin, as it sometimes is, it is very easy, especially with a pointed knife, to perforate it. For this reason it is well to use a special knife with a round-edged blade. Freer lays considerable stress on the necessity for thoroughly cutting through the mucoperichondrium, so that it may be raised from the subjacent cartilage. He says that if the perichondrium has not been divided on attempting to bare the cartilage the elevator will pass between the mucous and perichondrial layers, and it will be found to be an exceedingly difficult task to separate the mucosa from the perichondrium, whereas, as a rule, the whole muco-perichondrium can be raised without much trouble and frequently with surprising ease.

Separation of mucous membrane.—The flap outlined by the incisions is now stripped off the cartilage. This can usually be readily accomplished with a small, thin spatula, blunt-edged, and curved slightly on the flat. This curve facilitates working forwards from the vertical incision. In some cases there is considerable adhesion between the soft covering and the cartilage. The parts where adhesions are most frequently met with are the anterior region of the triangular cartilage, the summits of the angles of deflection, and along the incisor cres In these cases the mucosa must be carefully dissect off and for this purpose a sharp edged spatula is preferabl a perforation being less likely to be produced than by t blunt-edged instrument. After having bared the cartila over the area outlined by the incisions the part of t deflection behind the vertical angle is stripped of its coveri by inserting the spatula beneath the mucosa and free separating it until the whole of the convex side is denude A vertical slit is now made in the cartilage anterior to t commencement of the deflection (Fig. 3). This has to done with great care in order to avoid cutting through t mucosa of the concave side. It is best effected, I thi with a knife having a round-edged blade, the same, in fa as previously mentioned for making the primary incisio A finger should be placed in the opposite nasal fo in order that it may feel the knife before it c out through the mucous membrane. Through this the spatula is introduced and the mucous membr of the concavity separated from its attachment. There no greater difficulty in doing this than in clearing convex side, though frequently the mucosa is firmly adher in the deepest part of the hollow and the sharp-blac spatula will have to be employed. With a speculum in nostril of the concave side, the instrument can be s working its way beneath the mucous membrane, and it well, in order to avoid a perforation, that the curve of spatula should look towards the cartilage, as in this way edge is kept close to its surface. The operator should n assure himself that he has thoroughly separated the soft tissue from the area of deflected septum. This is most important, as if any of the mucosa remain attached it will be torn when the piece of septum is removed. Reliable indications of sufficient separation are the disappearance of the concavity and the straight curtain-like hang of the mucous membrane (Figs. 4 and 5). It now remains to remove the deflected portion of septum, which may be punched out piecemeal with Gruenwald's forceps, or some modification of this. Some operators speak highly of Killian's knife, which is a fork-shaped instrument with a small blade between the prongs of the fork, and is used for making the horizontal cuts at the top and the bottom of the deflection. Personally, I have found that the two horizontal and the posterior vertical incisions can be made very readily by employing two knives (designed by Freer) with short (about four millimetres) pointed blades at right angles to a long slender shaft. One is made so that it may be introduced under the mucous membrane to well behind the deflection; its point is turned towards the cartilage and a cut made from above downwards, dividing the cartilage behind the deflection. The blade of the other knife is so arranged that by inserting it to well behind the deviation and drawing it forward the cartilage is divided horizontally. Two of these horizontal incisions should be made, one above and the other below the deflection. It should now be possible to seize the portion of septum included by these incisions and to remove it in one piece. If the deformity were entirely cartilaginous the operation would now be completed and nothing remain to be done except to replace the flaps on what was the convex side. However, it frequently happens that the deflection extends into the bony part of the septum and when this is so its removal is

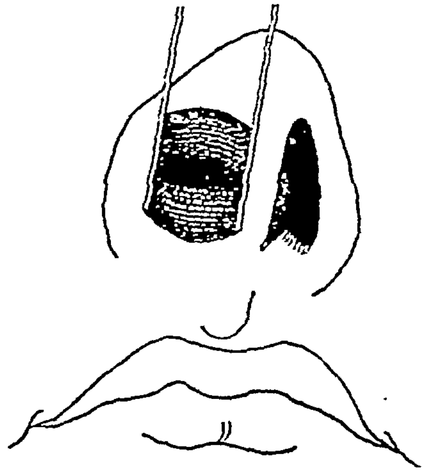
FIG. 3.



Dotted line *a* indicates first incision in cartilage.

rendered more difficult and tedious. The little rectangular knives which cut through the cartilage so readily are not applicable here. As a rule, all the upper part of the deflection may be cut away piece by piece with punch forceps without much difficulty. The most troublesome part to remove is the lower border of the vomer and the ridge of bone (incisor crest) with which it is articulated.

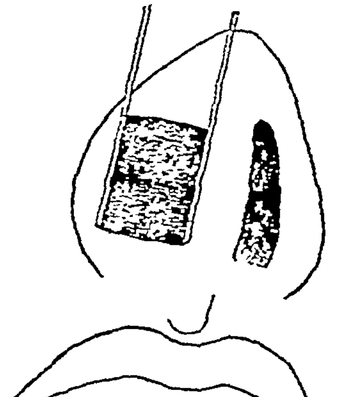
FIG. 4.



Showing the concavity before separation of the mucous membrane.

This is frequently included in the deflection, is very thick and hard, and forms a considerable part of the obstruction, so that its removal is absolutely necessary if a perfect result is to be looked for. In my experience I have not been able with the punch forceps to make any impression on this hard ridge. The two instruments which have proved most serviceable in my hands for this work are Killian's bayonet-shaped gouge and Bosworth's nasal saw.

FIG. 5.



Showing the straight "hang" of the mucous membrane after separation.

With the latter, even if one does not cut completely through the bony ridge, if a groove be made on each side, the attachment is weakened, and if then seized with punch forceps it can be broken off. The *operator should* now satisfy himself that he has thoroughly removed the deflected portion of the septum. If this be so, the flap on the convex side will hang down straight when replaced, the nasal passage on this side will appear freely patent, the posterior wall of the pharynx being readily seen, and on the concave side the hollow should be effaced. This is an important point, as if sufficient bone has not been removed the result is likely to be disappointing. The flaps are now replaced, and in order to keep them in position until adhesion has taken place it is a good plan to pack lightly the nasal fossa with short lengths of gauze (about two inches) wrung out in solution of peroxide of hydrogen (ten volumes) and laid one over the other. Done in this way, the gauze can be removed more easily, and if previous to attempting withdrawal it be moistened with peroxide of hydrogen there will be no likelihood of dragging the flaps out of position. The packing may be left in for 48 hours. It should then be carefully withdrawn piece by piece. All that is necessary in the way of after-treatment is to spray the nasal fossæ daily with an alkaline solution. Occasionally I have deemed it wise—in cases where the cavity was somewhat narrow and owing to swelling of the tissue there seemed to be some danger of the granulations at the edge of the flap contracting adhesion with the opposite turbinal—to insert a thin, nasal celluloid splint. This can be worn as long as may be considered necessary without causing any irritation. The advantage of the resection is more fully appreciated by the patient after about a month or six weeks, when the swelling incidental to the operation has completely subsided.

It has been contended by some that the time taken by the operation (sometimes between one and two hours) is a serious drawback, but I think no *one* who has had any experience of these cases can deny that the time is well spent and amply compensated for by the very excellent results which are obtained.

In conclusion, I have to acknowledge indebtedness to Dr. Otto Freer of Chicago for kindly permitting me to reproduce some of the diagrams from his valuable monograph.[1]

Queen Anne-street, W.

PRESENCE OF THE BACILLUS TYPHOSUS OR A CLOSELY ALLIED ORGANISM IN A SAMPLE OF DISTILLED WATER SUSPECTED TO HAVE CAUSED TYPHOID FEVER.

BY ROBERT W. C. PIERCE, M.D. LOND.,
MEDICAL OFFICER OF HEALTH OF GUILDFORD;
AND
JOHN C. THRESH, M.D. VICT., D.SC. LOND., &C.,
LECTURER ON PUBLIC HEALTH, LONDON HOSPITAL MEDICAL COLLEGE.

THE origin of so-called "sporadic" cases of infectious disease are rarely so fully investigated as they deserve. In a large number of instances the source of the infection is never traced, the medical officer of health either failing to find a clue or not having the necessary time to make a prolonged investigation. There can be no doubt, however, that careful and systematic inquiries into the source of infection in such cases would often lead to results of great epidemiological interest, throwing light on their origin and possibly revealing hitherto unsuspected modes of infection. The present article deals with one of these sporadic cases, the origin of which is fairly conclusively traced to the use of distilled water for potable purposes, and the investigations revealed also the possible means whereby the water or the vessel containing it became infected.

Towards the end of March last a man, aged 30 years, was notified as suffering from typhoid fever. On the seventh day of his illness his blood gave but a partial reaction with Widal's *test*, on the eleventh day the reaction was more marked, and about a week later the reaction was decided even with a dilution of 1 in 200. The clinical diagnosis was therefore fully confirmed and there could be no doubt about the nature of the case. There were no other cases in the neighbourhood, nor had there been any for a considerable period, and as we are no longer satisfied with the mere discovery of slight drainage defects as explaining the origin of these isolated cases very careful inquiries were made to ascertain whether any article of food or drink was, or had been, used by the patient but not by other members of the household. It was found that the patient alone used distilled water, drinking about a pint first thing every morning. The water was obtained in stone jars with wooden taps and the evidence was volunteered that the water was sometimes seen to contain a little fluffy material and that the jar had a suggestive odour of ginger-beer. It seemed barely possible that this water could have any connexion with the disease, but as no other more probable source of infection could be found a sample of it was taken for bacteriological examination. Various quantities of it were added to taurocholate glucose broth and the mixture was placed in the incubator. Quantities of five cubic centimetres and upwards produced acid, but no gas, and upon examination in the hanging drop it was found swarming with an actively motile bacillus which did not stain by Gram's method and which "clumped" when mixed with one-fortieth part of the serum from the patient's blood. From this growth plates were made on Conradi and Drigalski's medium when an abundance of colonies were obtained exactly resembling those of the bacillus typhosus. These results were so significant that whilst further bacteriological work was being undertaken inquiries were instituted with reference to the source from which the distilled water was obtained. The maker was interviewed and it was then ascertained that he had supplied a number of bottles of distilled water to a chemist in a town where typhoid fever was epidemic and that the bottle which contained the implicated water had been returned from this town. It was asserted, however, that the bottles were thoroughly steamed before being refilled and again sent out. This steaming does not appear to have sufficed in all cases to remove the odour of the ginger-beer which had previously been stored in these bottles, and it would probably be very difficult to sterilise effectually the wooden tap. In any case the bottle and tap had been in a town where typhoid fever was rife and possibly, nay probably, in a house in which there was a patient suffering from the disease, but this it was impossible to ascertain definitely since the chemist obtained a large number of bottles of distilled water at a time during the epidemic.

---

[1] Annals of Otology, Rhinology, and Laryngology, June, 1906.

The further examination of the water failed to detect the presence of the bacillus coli, though it was soon found that the taurocholate broth contained more than one organism. It is unlikely, therefore, that the water or tap had been contaminated by fæcal matter and how the particular organism ultimately isolated gained access to the water cannot be traced definitely. Two closely related bacteria were ultimately isolated and their characteristics are compared with those of the bacillus typhosus in the appended table. The bacillus A was the more fully examined since it more nearly corresponded with the bacillus typhosus and it will be noted that the only differences ascertained were that bacillus A produced a little more opaque growth on gelatin and on potato and was capable of producing acid in a broth containing saccharose.

—	Bacillus A.	Bacillus B.	Bacillus typhosus.
Growth on Drigalski's medium.	Violet blue colonies.	Violet blue colonies.	Violet blue colonies.
Growth on gelatin.	Like bacillus typhosus but a little more opaque.	Like bacillus typhosus but a little more opaque.	Typical.
Growth on potato.	Not so visible as B; more than typhosus.	Very visible, dirty, creamy.	Almost invisible.
Growth on bile-salt neutral red agar.	White colonies.	White colonies.	White colonies.
Bile-salt glucose broth.	Acid; no gas.	Acid; no gas.	Acid; no gas.
Neutral-red agar, shake culture.	No fluorescence.	Fluorescence.	No fluorescence.
Litmus milk.	Acid slowly formed; no clot or bleaching.	Acid and clot in two days. Bleaching effect.	Acid slowly formed; no clot or bleaching.
Indol in broth.	A doubtful trace.	None.	A doubtful trace.
Lactose broth.	No acid or gas.	No acid or gas.	No acid or gas.
Mannite broth.	Acid only.	—	Acid only.
Dulcite broth.	No acid or gas.	—	No acid or gas.
Saccharose broth.	Acid only.	—	No acid or gas.
Widal's reaction.	1 in 30, marked.	1 in 30, distinct.	1 in 30, distinct.
"	1 in 50, less marked.	Not so marked.	1 in 100, distinct.
"	1 in 100, *nil*.	1 in 100, *nil*.	—

The above reactions show that the bacillus A very closely resembled the bacillus typhosus and that it was not nearly allied to the bacillus coli communis, the bacillus enteritidis, or the paratyphoid bacilli. We are inclined to think that to its presence in the distilled water the attack of typhoid fever was due. In any case the coincidence of the presence of such an organism in an article of drink used exclusively by the one member of a family attacked by typhoid fever appears of sufficient interest to be worth recording.

SOME REMARKS ON THE THERAPEUTIC ACTION OF THE IODIDES.[1]

BY JAMES BURNET, M.A., M.D. EDIN., M.R.C.P. EDIN.,
SENIOR CLINICAL TUTOR AT THE ROYAL INFIRMARY, EDINBURGH; REGISTRAR TO THE ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH; AND PHYSICIAN TO THE MARSHALL-STREET DISPENSARY, EDINBURGH.

THE iodides belong to that class of remedies familiarly known as alteratives, that is, drugs which influence nutrition in some undefined way and possess a definite effect upon the bodily metabolism. The iodides are derived from the non-metallic element iodine, and possess in many respects a somewhat similar action. The potassium salt is the one most frequently employed, and it is with special reference to its therapeutics that I wish now to speak. Iodine is a remedy of great antiquity, but its true therapeutic effects were probably not well recognised until after the beginning of the nineteenth century. It was, perhaps, as an antisyphilitic agent and as a remedy against scrofula that we find it most largely employed by those earlier workers. Ricord especially advocated iodide of potassium in syphilis, while Trousseau warned against its being prescribed in exophthalmic goitre. In France a remarkable paper appeared by Delioux in the year 1855 on the treatment of chronic rheumatism and gout by means of iodine. In 1879 Germain highly commended potassium iodide as a remedy in respiratory affections and as an agent which modified very definitely the bronchial secretions. Dieulafoy had already used iodine injections in the treatment of ascites and of purulent pleurisy and we find Trousseau following his method in cases of the latter disease. Balfour early in the "sixties" strongly advocated the use of potassium iodide in the treatment of aortic aneurysm and in this view he was supported by men like Bouillaud who had already in 1859 recorded cases of aneurysm successfully treated in this way. It is probably to Graves, a Dublin physician, that we owe the suggestion of using large doses of iodide of potassium in painful affections of the fasciæ and nerves. Such, then, is a very brief historical retrospect which might well be followed out more fully by any of you who are interested in the history of therapeutics.

I shall now pass in review some of the therapeutic indications which we have established for the use of the iodides, especially the potassium salt. And first, I think, we ought to look at its use in cases of aneurysm. Probably no single known drug acts so beneficially as does potassium iodide in this terrible affection. But what is its *modus operandi?* That is a question by no means easily answered. Balfour[2] maintains that "by the use of potassium iodide we lower the blood pressure sufficiently to enable the natural elasticity of the arterial coats to contract the aneurysmal sac temporarily." He further states that this remedy does not increase the coagulability of the blood but rather produces a greater fluidity. The aneurysm, according to this clinician, is cured not by the formation of solid coagula within the sac but by hypertrophy of the muscular coat where that still exists and of the adventitia, with concomitant contraction. Such, at all events, was the condition of matters found on post-mortem examination in all cases of aneurysm which he treated with iodide of potassium and which showed any measure of success. He also says that "*we may accept uniform dilatation of the arterioles as the cause of that lowering of the blood pressure which forms so important an element in the treatment of aneurysm.*" Now, let us for a moment consider these statements. First, as to the effect of potassium iodide on the coagulability of the blood. For my own part I believe that potassium iodide always tends to render coagulation of the blood more ready of accomplishment and that it is to the formation of a firm clot within the aneurysmal sac that the contraction of the latter is due in cases which are benefited by this treatment. In support of this view I would instance the results obtained from the administration of iodides in cases of hæmophilia. The cure here, if cure it can be called, is undoubtedly effected by this very blood-coagulating property of the drug in question. Then, again, when we come to consider the effect of iodide of potassium on the blood pressure we are bound, I think, to admit that Balfour's views are quite untenable but we must look a little more carefully at this interesting question before coming to a decision on the matter.

---

[1] A paper read before the Therapeutical Society.

[2] Clinical Lectures on Diseases of the Heart. Third edition, p. 439.

The administration of iodide of potassium by the mouth has, in my experience, no effect whatever, either upon the pulse-rate or blood pressure within the arteries. It might be otherwise, however, were the remedy given hypodermically. Accordingly, with a view to determining this important matter I made use of iodipin injections in a variety of cases, including aneurysm, arterio-sclerosis, angina pectoris, asthma, and tertiary syphilis. Iodipin is a chemical combination of iodine and sesame oil. I always employed a 25 per cent. strength and found that it possessed the great advantage of being very tardily eliminated from the body after its injection under the skin, whereas iodide of potassium given by the mouth is all eliminated within 24 hours. Being a viscid, oily liquid it should be heated to body temperature before being injected and a serum syringe should always be employed having a capacity of from 10 to 20 cubic centimetres. The injections are best given under the skin of the abdomen, which is first, of course, thoroughly sterilised, and after the injection the puncture should be closed by means of surgical plaster. Another point to attend to in giving the injection is to avoid using massage which only tends to produce irritation and is, moreover, quite an unnecessary procedure. I found that a 15 cubic centimetre injection every second or third day was quite sufficient and very often I found that I could discontinue the iodipin treatment for intervals of a week at a time without detracting from its therapeutic effect. Now the result of this hypodermic method of administering iodides so far as the heart and blood-vessels were concerned was practically negative. In no case was the blood pressure altered, nor was the heart's rate or rhythm affected. Especially I found that the heart's action was never increased or depressed and that the pressure within the radial artery when markedly high to begin with was never lowered, even after a prolonged use of the iodipin injections. Still, all the same, I had good results in nearly all my cases, results which were achieved without that amount of gastric disturbance and loss of appetite which invariably accompany the prolonged oral administration of iodides.

Stockman[3] has already given us his own experience, although his paper refers more especially to the effects produced by potassium and sodium iodide when given by the mouth. He employed doses of 15 to 30 or 40 grains a day in a variety of conditions and found that in no case was any fall in blood pressure recorded or any change produced in the rate or the rhythm of the heart. He therefore concludes that iodide of potassium when given in therapeutic doses by the mouth does not modify the physical condition of the circulation, neither does it directly weaken the heart nor dilate the arterioles. This is exactly in accord with my own findings in the case of iodipin injections, although it is in direct opposition to the teaching of many text-books which maintain that potassium iodide has a definite effect in reducing blood pressure, and it is on this assumption, doubtless, that the majority of practitioners order it to be taken in cases of aneurysms, arterio-sclerosis, and allied affections. This, however, is to my mind erroneous teaching and will not stand the test of careful bedside investigation which, after all, is the best criterion, worth more than volumes of laboratory reports and animal experimentation. But we have not yet settled the question as to how it is that iodides act so beneficially in cases of aneurysmal dilatation. Probably it may be conceived that they do good by eliminating those poisons which have produced the arterial degeneration and by removing from the vessel coats the pathological material deposited upon them in the course of the disease. As a natural result the normal elasticity of the vessel walls is restored and the aneurysmal sac gets a chance to contract. Or, again, it may be considered that iodides cure aneurysm because the latter is a result of syphilitic infection and that by virtue of its antitoxic action on the syphilitic virus iodide of potassium does good. Unfortunately all aneurysms are not of syphilitic origin. I have seen cases where syphilitic infection was out of the question and all of you must be familiar with such examples. The antisyphilitic theory, therefore, is not supported by facts. I am inclined to believe that its sole effect is to aid in the coagulation of blood within the sac and I point to the value of potassium iodide in certain cases of hæmophilia in support of my opinion. Otherwise I am afraid we are still in the dark as to the true therapeutic action of iodides in cases of aortic aneurysm.

If we now look at the effect of iodides on arterio-sclerosis we find ourselves face to face with a similar difficulty. Within recent years Vierordt has asserted that iodides alleviate, and may even actually cure, vascular degeneration. He begins with small doses of two or three grains given two or three times a day and goes up to 15 grains thrice daily. He continues this administration for a period varying from one and a half to three years with occasional intermissions. His results have been uniformly excellent, even in cases, remember, which were non-syphilitic. He gave iodides on the assumption that they promote resolution of the sclerotic process in the blood-vessels. We also find Huchard advocating their employment in similar cases. He says[4] that iodides combine with their influence upon the peripheral and visceral circulation which they accelerate, upon the nutrition of organs which they render more active, and on arterial pressure which they lower, a no less important resolving action on the sclerosed tissue and vessel walls. He found by experiment with the manometer that after intravenous injection of potassium iodide in animals he obtained as much as from 10 to 40 millimetres of a fall in the mercurial column so far as the carotid artery was concerned. These falls in the mercury were produced in from 10 to 30 minutes after the injection of the drug in doses of 50 centigrammes per kilogramme of body weight. These results are quite at variance with those obtained by Boehm and more recently by Prévost, Corin, and Stockman in so far as the sodium salt is concerned. With potassium iodide it is otherwise, for Stockman finds that when it is given intravenously it has a marked depressant action on the heart. Small doses, however, produce a transient rise in blood pressure with slowing of the cardiac action. The depression is doubtless due to the effect of the potassium and not at all to the iodine contained in the salt. This intravenous effect, however, must be put out of account altogether, for we never administer iodide of potassium thus in practice. When we give this drug by the mouth it circulates in the blood in a very much diluted state and so cannot possibly depress the heart as it would do if injected into a vein when it would then reach the heart in concentrated form and so lead to its characteristic potassium effect, as Stockman is careful to point out. I have gone into some detail on those points as I wish to warn you against applying to clinical practice results which have been obtained on animals in a laboratory under artificial conditions and by means which are not employed in the practice of medicine at all. It is a pity that in these days laboratory experiment is so rapidly replacing the older fashioned but, to my mind, much more convincing bedside observation. At all events, I have taken the trouble to satisfy myself that even by the hypodermic injection of iodipin in cases of arterio-sclerosis no effect on the actual blood pressure is to be expected. If it does good in these cases it is, I think, by its power of elimination, thus enabling the blood to get rid of irritating matters and waste products and thus aiding in the readier circulation within the sclerosed vessels. Potassium iodide when given by the mouth is very rapidly absorbed and is probably largely converted into the sodium salt in the body.

In connexion with the problem of the action of iodides in cases of arterio-sclerosis I may perhaps refer to the question of how far the iodides affect the excretion of uric acid. They certainly tend to diminish it. Haig[5] found that if the excretion of uric acid was high it was at once reduced by the administration of iodide of potassium and that when the effect of the drug had passed off the excretion once more rose. He maintains that this lowering of urate excretion is not due to its destruction or elimination in other forms but to its actual retention in the body. The iodide probably renders the blood a bad solvent of urates, and so they are retained, but when the effect of the remedy has gone the blood takes up the urates again and accordingly they are *excreted by the urine in excess. In his* paper on the Effects of the Iodides on Arterial Pressure Haig[6] refers to their specific action in relaxing the arterioles and says that this result, together with the diuresis they produce, is contemporaneous with a diminished excretion of uric acid in the urine. His idea is that arterial pressure is not influenced by the iodides themselves but by their effects on the solubility of the uric acid and the amount of this substance present in the blood, and he bases this opinion on the fact that quite a number of drugs produce a reduction in arterial pressure together with a diminution in uric acid excretion. There is, I think, a good deal to be said in favour of this view of the action of the iodides in cases of arterio-sclerosis, although I think Haig *is quite beyond the mark in supposing* that the iodides affect the blood pressure. I am inclined, however, on the whole, to favour his uric acid excretion theory, as many cases of arterio-sclerosis, especially those of toxic origin, are benefited when iodides are given on this assumption.

[4] Maladies du Cœur et des Vaisseaux, Paris, 1899.

[5] Uric Acid in the Causation of Disease, London, 1903.

I wish to say a word or two now regarding the employment of iodides in cases of angina pectoris. I am of opinion that to be of any real service the patient should have from 30 to 60 grains per day and that this administration should be kept up for months. A patient under my care some time ago for the disease was given one and a half drachms of iodipin in warm milk three times a day for periods of a month with a week's interval between for a year. During that time he had no attack, although previously he had one on an average every four or five months. Huchard, whose knowledge of heart affections must be considered very extensive indeed, did not hesitate in severe cases to give as much as from 12 to 15 or even 20 grammes of iodide of potassium in a single day. This may be by some regarded as heroic treatment but I think it was fully justified by the results obtained. Arterio-sclerosis, which is so often present in these cases, is not necessarily a source of heightened blood pressure. Rolleston[7] points out that the iodides in such cases act by stimulating the secretion of the thyroid and not by their depressant effect upon the circulation. In this connexion I may refer to a paper by A. Fraenkel[8] in which he says that the pathology of angina pectoris is to be found in a sclerosis of the coronary vessels, the angina occurring in the course of syphilis, gout, and aneurysm being due to this. In other cases a spasm of the smaller vessels of the heart produces an anæmia and the pain thereupon ensues. This spasm, which is probably the source of every attack of true angina, is relieved by the use of iodides, of which the author prefers the sodium preparation as less likely to interfere with digestion. This view of the treatment of angina by means of iodides is, I think, a very rational one and is to some extent in accordance with my own opinion to which I shall presently refer—namely, that iodides relieve angina by their specific antispasmodic action.

Passing now to the *consideration of the therapeutic* action of the iodides in cases of respiratory disease we find ourselves on less uncertain ground. I may say that it is with this sphere of their action that I am most familiar. In chronic diseases of the respiratory system I know of only two or three remedies which may be absolutely relied on and one of these is the iodide of potassium. Some three years ago, while *I was engaged in making a series of observations* on pulmonary fibrosis as met with in stone-masons, I found that the two drugs which were of most value were iodide of potassium and ichthyol. With these two remedies alone I was often able to alleviate the symptoms very materially indeed. When the dyspnœa which in such cases generally results from emphysema becomes a marked feature of the case then iodides given regularly *over a somewhat prolonged* period almost always afforded relief from this distressing symptom. Here it was that I first discovered the superiority of iodipin over iodide of potassium. Its action is more prolonged as its elimination is more gradual than that of the potassium salt. It is also absorbed much less rapidly and so tends to have a more uniform effect upon the tissues with which it is brought into contact. After administrating iodipin for some time traces of iodine may still be found in the urine many weeks after the treatment has been stopped. It is stated that iodipin is practically not split up in the stomach but is absorbed from the intestinal canal. The iodine, however, apparently remains firmly adherent to the fatty acids and probably only a minute quantity is given up owing to the alkaline action of the intestinal juices. The greater portion of the iodipin is oxidised in the body and when this oxidation takes place all the iodine separates out as iodide. This oxidation, however, is slow and compared with iodide of potassium the elimination is, as I have already remarked, more protracted. For these reasons I prefer it in all cases of respiratory disease. The 10 per cent. strength can be given in one or two drachm doses by the mouth, mixed with a little warm milk, three times a day, or the solid form of iodipin may be employed. The latter is a brownish-coloured substance and may be had in rather large, sugar-coated tablets. The solid form gets rid of the objection which some patients have to the oily liquid. Roughly speaking, one drachm of 10 per cent. iodipin is equivalent to eight grains of potassium iodide. But not only do the iodides relieve the dyspnœa in cases of the kind referred to but they have an additional and very valuable therapeutic effect. I find that all these cases of pulmonary fibrosis complain of distressing cough and difficult expectoration most marked in the early morning. In such cases I always obtained the best results by giving a full dose of iodipin at bedtime. By this means the contents of the bronchial tubes are liquefied and expectoration is thereby facilitated. The remedy should, I think, be given on an empty stomach in order to obtain the best results.

In chronic bronchitis, too, especially in elderly patients, the iodides are extremely valuable if given half an hour before meals in a small amount of water, not, as is sometimes advised, a glassful. Here, again, a single large dose of, say, 15 grains given at bedtime acts like a charm. I have heard it stated that it is folly to give so depressing a remedy to old people, but *so far as my experience goes* nothing but good results follow when it is given in this way. Sometimes it may be given thrice daily in smaller doses, say, five grains, but I do not think the result is then quite so satisfactory or striking. I have known it produce in certain cases, especially when given regularly three times a day, a considerable amount of gastric disturbance. This is probably due to a condition of hyperchlorhydria and I have often been able to alleviate the stomach trouble by combining ammonium carbonate with the iodide. Asthma of true bronchitic origin is, again, a disease in which the iodides are often of great service. They are best given here in fairly large doses, say 10, 15, or even 20 grains every two or three hours for some time. Haig[9] holds that iodides relieve asthma by clearing the blood of its contained uric acid and so reducing the blood pressure and the resulting congestion in the area of the bronchial arteries. My own view is that in this disease the iodides have a real antispasmodic effect, probably by virtue of their action, when given in full doses, upon the nervous mechanism. I have often wondered if this theory might not explain the good results which one so often sees following the administration of potassium iodide in cases of angina pectoris, when given continuously in fairly large doses between the paroxysms. In the treatment of bronchitic asthma, as indeed also of angina, it is well to bear in mind the possibility of securing more lasting effects by substituting *iodipin and even in the worst* cases by giving the latter hypodermically. I think that in every case of asthma there is always a certain amount, sometimes a considerable amount, of associated spasm of the bronchioles, and when this is relieved, as I maintain it can be, by iodides, then the disease may be said practically to be cured. The probable antispasmodic action of the iodides is one which, at all *events, deserves careful* clinical investigation in a large number of cases before it is set aside as untenable. In bronchitic asthma, at any rate, the iodides may be confidently relied on to produce good results if properly administered. I mentioned their use in the emphysema associated with pulmonary fibrosis but they are equally beneficial in the emphysema which results from chronic bronchitis.

Turning to the administration of iodides in syphilis, we find them most advantageous in cases where the mucous membranes, bones, and nervous system are involved. I need not dwell long on this field of iodide administration as it is so familiar. I would, however, emphasise the fact that the hypodermic treatment of syphilis in this country is not very actively carried out. I firmly believe that by early hypodermic mercurial treatment combined with systematic and very thorough inunctions continued over a prolonged period with intermissions we would be able to secure absolute immunity from all the so-called tertiary manifestations of this disease, such as glossitis and vascular changes, together with the numerous spinal and cerebral affections so commonly met with in practice. So, too, in the treatment of tertiary syphilis I am a strong upholder of the hypodermic method of treatment, and here I am fond of using the 25 per cent strength iodipin. Of course, this means a little extra trouble on the part of the physician, but the results secured will repay the additional time expended on the treatment of these cases. I do not, of course, for a moment suggest that the oral administration of iodides is without effect but I do maintain that it is not so lasting in its results or so quickly successful as when the hypodermic plan of treatment is followed. Large doses ought certainly to be given in syphilitic cases, and especially in nervous lesions, notably locomotor ataxy. In the last-mentioned disease I have given as much as 120 grains of iodide of potassium in 24 hours with very marked benefit. The patient actually put on weight under its administration and lost altogether his troublesome gastric attacks which he complained of specially when he first came under observation. These are the cases in which I think we ought to try iodipin injections, and when opportunity offers I intend to try this method of treatment. Already I have found it succeed admirably in a case of syphilitic cephalalgia attended by twitchings of the left hand which I attributed to pressure of a gumma. The twitchings ceased entirely after the tenth injection, and the headache was distinctly lessened after the third. The effects of iodides on late syphilitic lesions is probably simply due to their eliminating action, but it must not be forgotten that iodides have been, and are still, employed as antitoxic agents. For example, Tarnier employed them in the treatment of puerperal fever and for purposes of disinfection, while Donard used iodide of potassium as a remedy in cases of intermittent fever, and others have used this drug with success in the treatment of erysipelas. It is probable, therefore, that the iodides have a twofold action in cases of tertiary syphilis, first of all, by producing an antitoxic effect, and secondly, by bringing about a more or less rapid resolution of the products of the disease. We must, however, give the iodides in full doses here so as to bring the patient thoroughly under their influence, otherwise they cannot be expected to do much good. By leaving off the administration at intervals and by gradually increasing the dose the patient's tolerance of the drug can usually be guaranteed.

[9] Op. cit.

The treatment of chronic rheumatism by means of iodides is a matter of some little interest. For my own part I believe that the iodides do good in these cases by virtue of their effect upon the uric acid excretion. If we give iodides to a patient who is suffering from chronic rheumatism, or from such conditions as sciatica, lumbago, or neuralgia, produced by exposure to cold or wet, and whose urine is acid, then we find that very soon after we have begun our treatment the urine becomes less acid and may even tend to become alkaline in some cases. Haig calls attention to this fall in urine acidity accompanying diminution of uric acid excretion produced by the iodides. He suggests that the retention of uric acid produced by iodides may be the result of some effect upon the phosphates of the blood, although he admits that there are no known chemical data which support his opinion. In cases of chronic rheumatism I prefer to combine the iodide administration with salicylates, the latter acting by eliminating the uric acid while the iodides prevent the uric acid combining with an alkali in the blood. In this respect I am a disciple of Haig, who maintains that it is this combination of uric acid with an alkali or with neutral phosphates in the blood which produces all the physiological and pathological effects which he has been led to attribute to uric acid. (I am here practically quoting Haig's own words.) Small doses of iodide of potassium suffice in cases of chronic rheumatism. Five to ten grains given thrice daily in soda or potash water is a sufficient amount

I can only refer to the use of iodides in cases of effusion. They act here by elimination and are of very great service. Their beneficial effect is also manifested in all kinds of chronic inflammation. In cases of interstitial nephritis iodide of potassium has been tried with some success. It acts by virtue of its diuretic power and should be given in doses of from ten to 30 grains, or even more, three times a day well diluted. Hepatic cirrhosis is likewise a disease which sometimes improves under iodide treatment. Then, again, in cases of metallic poisoning, notably lead and mercurial poisoning, iodides may be confidently relied on to do good. In chronic metallic poisoning we find the metal accumulating in the body by reason of its affinity for albuminoids. During the constant metabolic changes going on within the body the poison is set free. When we give iodides in such cases we find that the metal breaks away from the albuminoid substances and is eliminated in the form of insoluble salts.

And now, lastly, a word or two as to the employment of the iodides in cases of goitre. Kocher, in a paper which I cannot now lay hold of and which was published a year or two ago, found that when the thyroid gland was normal it took up the iodine when iodides were administered and eliminated it rapidly again. This was not so when the thyroid was diseased. In some cases he found that an abnormal amount of iodine was taken up by the gland and eliminated in excess, while very often in these very cases signs of iodism were observed. He advised that iodides should be given very early in cases of thyroid enlargement and in small doses. Sometimes good results were obtained but, on the other hand, the treatment was often unsuccessful. In cases of exophthalmic goitre iodide of potassium is sometimes employed in the hope of reducing the circulatory force, but Trousseau distinctly warns against its employment in this disease. I think, however, that I have had good results from its adoption in at least one case, although I cannot say that it slowed the pulse or checked the severe palpitation from which the patient suffered. I think if it does good in these cases it must be by its direct action upon the gland itself the function of which has probably become materially affected by the disease process.

Such, then, is a very imperfect survey of some of the therapeutic uses of the iodides. We know comparatively little of the rationale of their action, but at all events I think we are able to formulate certain working hypotheses which are helpful in actual practice. Our lack of knowledge is largely owing to our neglect of clinical experiment and observation. Even the every-day country practitioner may discover new uses for old remedies and fresh reasons for their employment because he is daily working in nature's medical laboratory—the sickroom. The history of the employment of the iodides is largely a history of the progress of medicine, for doubtless we can conceive, for example, of their being first used empirically in the treatment of cough, until one day it was discovered that the cough was associated with emphysema and so they became the favourite in the treatment of this disease. Yes, we may now order the iodides somewhat ignorantly but one day we will by patient effort obtain more light on their therapeutic action in disease.

I think it is a pity that we do not employ the sodium salt more frequently than we do. It is less likely to interfere with digestion and is quite as efficacious as the potassium is. It is well also to bear in mind that the hypodermic administration of the iodides in the form of iodipin is a useful adjunct to treatment, notably in syphilitic disease of the nervous system and in all chronic inflammatory conditions. It possesses the advantages of being more intensive in its action, less upsetting to the stomach, and requiring less frequent administration. Perhaps some of you who have listened so patiently to my remarks may feel that I have added little to your knowledge of the therapeutics of the iodides but I trust that at least I have been able to awaken renewed interest in the subject and have given some of you an impetus to further study which some day will bear fruit in the shape of added knowledge on a subject which at present is beset with untold mysteries.

Edinburgh.

BORIC ACID IN FOOD.—At the Bradford-on-Avon (Wiltshire) petty sessions, held on August 29th, a tradesman was fined £5 and costs for selling milk containing at least 20 grains of boric acid to the pint.—At Camborne (Cornwall), on August 21st, a grocer was summoned for selling adulterated German sausage. Analysis showed that the sausage contained 45 grains of boric acid to the pound. The defendant stated that the German sausage was manufactured in England. After some discussion the magistrates fined defendant 1s. and costs, and stated a case for appeal, the chairman remarking that it would be as well to know what quantity of boric acid was permissible.

THREE CASES OF TWISTED PEDICLE.

By W. GREENWOOD SUTCLIFFE, F.R.C.S. Eng.,
HONORARY SURGEON TO THE ROYAL SEA-BATHING HOSPITAL, THE MARGATE COTTAGE HOSPITAL, AND THE VICTORIA CHILDREN'S HOME, MARGATE.

The first case, seen with Dr. A. Warwick Brown, was that of a child barely 15 years of age who had been under his care for some days as one of a group of cases of epidemic roseola when she was seized at night with abdominal pain on the right side, coupled with tenderness and a temperature of 100° F. On the next day the bowels acted normally, the pain subsided, but the temperature rose again to 100° at night. On the following day (June 13th) I saw her with Dr. Brown. We found the tenderness less and no definite lump or swelling in the abdomen; the tongue was furred. There had been occasional retching and an enema given earlier in the day had not been returned. The temperature was 100·6° and the pulse was 90. The case presented the symptoms of a mild attack of appendicitis and as the symptoms appeared to be subsiding we thought it best to wait before deciding on operative interference. On June 14th there was a large dull area in the right iliac fossa. The temperature was 101° and the pulse was 100. An enema given two hours previously to the consultation had been ineffective and the child was obviously a little worse than on the day before. An operation was accordingly decided on and, acquiesced in by the parents, took place the same afternoon. The diagnosis being appendicitis the oblique intramuscular incision was adopted and though some blood-stained fluid was present in the peritoneal cavity the cæcal region was soon seen to be normal. At the lower angle of the wound a thin-walled cystic tumour was discovered and this, examined after prolonging the wound downwards, was found to spring from the left broad ligament. The cyst was tapped and delivered; its pedicle, to which the ovary was attached, was twisted three or four times on itself and the ovary was in a highly engorged and hæmatomatous condition. The pedicle was tied off and the ovary and cyst (a thin-walled unilocular specimen) were removed. The abdomen was sewn up in layers and the patient made an uninterrupted recovery.

The case resembled so closely an attack of appendicitis and the patient was so young that the possibility of ovarian disease was overlooked until actually preparing for the operation, when the ovarian instruments and ligatures were put out as a matter of routine. There was very little extra difficulty on account of the position of the incision as there were no adhesions to be dealt with.

The second case, that of a working girl, aged 21 years, is of interest solely because it forms one of a series of three similar conditions seen in a few weeks. On the night of July 9th the patient had an attack of violent abdominal pain, localised after a time to the lower part and right iliac fossa, with frequent attacks of vomiting. I was sent for early on the 10th; there was then to be made out a fluctuating tender tumour, slightly moveable, and nearly median, extending from the pubes to a little above the umbilicus. Per rectum the uterus could be felt displaced backwards and downwards by the swelling which filled up the pelvis. There was a history of occasional spasms of pain in the lower part of the abdomen for about a week but the girl had kept on with her work until the night before when she had to give in. The temperature was 99·2° F. and the pulse-rate was scarcely at all accelerated. She was removed to the Margate Cottage Hospital, some three miles off, and I operated the same afternoon. The cyst was exposed, tapped, and brought out through the usual median incision. The pedicle was twisted three times on itself, so that the cyst, which sprang from the left broad ligament, was inclined to the right side. As in the previous case, the cyst was unilocular and the ovary, intensely congested and inflamed, was adherent to its base. There was no adhesion of any sort. The pedicle and the abdomen were treated in the usual manner and the patient recovered without any unusual symptoms.

The third case was that of a single woman, aged 48 years. The patient was sent to me by my friend Mr. E. Moon of Broadstairs. She was a more than usually voluble Irishwoman who went to him a week previously to my seeing her and complained of pains in her right hip which she ascribed to rheumatism and refused any suggestion of examination. Four days afterwards she took to her bed and Mr. Moon was sent for. She then had intense abdominal pain, especially in the right iliac region, where a hard swelling could be felt but as she still objected strongly to any sort of examination no real diagnosis was made. The bowels not having acted for several days enemata were given on that and the next day, but without result. On the evening of July 17th the patient was admitted to the Margate Cottage Hospital and then had the following appearances. The whole abdomen was tender and though any attempt at manipulation was intensely painful a hard mass could be felt in the right iliac fossa and a sense of resistance extended from it to well to the left of the middle line. Per rectum the cavity was found compressed by a hard mass occupying the pelvis and the uterus was not made out. The temperature was 101° F., the pulse was 100, and the patient was obviously very ill. Operation was proceeded with almost at once and the mass in the right iliac fossa becoming very definite when the patient was under the anæsthetic it was decided to incise through the sheath of the right rectus so as to come directly on the swelling. There was a considerable amount of blood-stained fluid in the abdomen and the swelling when disclosed was found to lie on the right pelvic brim and to project on the cæcum and appendix, to both of which it was attached by loose adhesions. These were easily separated and the growth was brought out of the abdomen. It was then seen to be a semi-solid ovarian cyst connected with the right broad ligament with a pedicle twisted into a knotted rope-like cord. The pedicle above the twist and the tumour were blackened and congested from the effects of the torsion, and there was a good deal of oozing from the bed it had made for itself. The pedicle having been tied and the tumour cut away the pelvis was examined and a large white walled semi-fluid tumour was found blocking up the whole pelvis. Its connexions were only made out after freely enlarging the incision in both directions. It sprang from the left broad ligament, pushing the uterus against the pubes; it filled out completely the retro-uterine pouch and its wall was adherent to, and continuous with, the peritoneum covering the upper part of the posterior vaginal wall. On the right side there were adhesions to the right broad ligament which was flattened out against the pelvic wall. The tumour was tapped and a large quantity of dermoid contents was let out but it still remained of considerable size and a tedious separation of adhesions followed by some force was necessary before the tumour was eventually brought out of the abdomen. The pedicle, mixed up with firm adhesions on the left side, was unsatisfactorily defined and the removal of the tumour was followed by some smart hæmorrhage. A search of the left broad ligament for its sources followed; these branches of ovarian vessels were discovered and double ligatured, the remains of the Fallopian tube were removed, some more bleeding points were dealt with, and after the insertion of a large rubber and gauze drain the abdominal wall was closed. From the drainage-tube left in for 36 hours some blood-stained serum, possibly a few ounces, was discharged. On the next day the patient's temperature was 100·6° and the pulse was 120, but there was neither vomiting nor distension, and a large enema on the second morning followed by a dose of magnesium sulphate on the third were each effective in relieving the bowels of their eight days' accumulation. The patient's progress after that was uninterrupted and uneventful.

The patient was entirely oblivious of the presence of these tumours, her only previous illness being occasional epileptic fits. The right tumour proved also on examination to be of a teratomatous character, containing, besides the usual semi-solid contents of such tumours, a quantity of iron-grey hair. It was of the size of a large lemon and was unilocular. The larger specimen from the left side was multilocular, each cavity containing hair, teeth, and the usual thick liquid. There were also nipple-like projections from the walls of two of the three chambers into which the cyst was divided by well-marked partitions. When full the cyst was nearly the size of a man's head.

In this case the gradual enlargement of the left cyst had pushed its companion out of the pelvis where in its endeavour to settle down comfortably the torsion of the pedicle had been brought about, giving rise to the already quoted pains in the patient's right hip, which was the first recorded symptom of the presence of the tumours. Bilateral teratomata are described in text-books as "occasionally" occurring, but they certainly form a sufficiently rare variety of the acute abdomen to deserve recording.

I have to thank my colleagues, Dr. R. Thomson and Dr.

J. L. Sawers, for their assistance in dealing with the first and third of these cases, and Mr. B. Moss for assisting me with the second and anæsthetising the third.

Margate.

A PRESUMED CASE OF ACUTE YELLOW ATROPHY OF THE LIVER.

By W. CURLING HAYWARD, M.B., B.S. DURH., M.R.C.S. ENG., L.R.C.P. LOND.,
DIRECTOR OF THE GOVERNMENT HOSPITAL, PORT SAID.

SOME weeks ago I saw in THE LANCET the report of a case of supposed yellow atrophy of the liver. I have had a very similar case in my practice here and I think that, as these cases are so rare, when one occurs it should be put on record. My case is as follows.

On May 27th I was asked to see a case of jaundice in consultation with another medical man. The patient was a male Arab, aged 40 years, of fine physique and intelligence. He had been ill with jaundice for eight days. His family history was good; his habits were also good; he was a non-drinker and non-smoker. The patient began to feel ill on May 19th, eight days before I saw him. The onset was sudden; there was a slight rigor, with malaise, vomiting, and fever. He took a purge, as is the custom with natives, but this did him no good. Next day he saw that his eyes were yellow, his urine was dark, and that his stools were clay-coloured. He saw a native doctor who gave him a dose of some medicine and a blister for his stomach. The jaundice and vomiting increasing he sent to the hospital. My assistant, Dr. Obarawy, went to see the man, and thinking the case was one of simple catarrhal jaundice he gave the patient a saline draught and prescribed a liquid diet. No improvement taking place I was asked to see the sick man. When I arrived at the house I saw him sitting on his bed cross-legged, which position gave him most relief. There was deep jaundice of the conjunctivæ, the skin had a bronzy tinge, and the man looked ill. He complained of some headache, some abdominal pain, and loss of appetite. I took the temperature and found it to be 99·5° F., the pulse was 88, full, regular, and soft, the tongue was furred, and the breath was foul. I then proceeded to make an examination but found nothing. The spleen was not enlarged, the kidneys were normal, no gall-bladder could be felt, and no tumour in any part of the abdomen. The chest was free from disease. On percussing the liver there was some tenderness in the intercostal spaces, but the only painful spot was in the epigastrium, and that was caused probably by the previous treatment. On making a very careful examination of the liver dulness I could not say for certain that there was any decrease of its size and my assistant also could not say for certain. I also treated the case as one of simple catarrhal jaundice. I took away some of the urine to examine, more for experimental purposes than any other reasons. When I had evaporated a drop on a slide and examined it under my microscope, to my great surprise I saw large masses of tyrosin crystals and leucin plates. Then I saw the nature of the case that I had to deal with. Later in the evening I heard that the man was feeling better and his vomiting had stopped. Next morning I was sent for hurriedly. On getting to the house I heard that the patient had become delirious in the night and had tried to throw himself out of window. I then went into the room, the man did not know me; he was lying on his bed apparently asleep. I spoke to him but he refused to take any notice of me, so I tried to turn him towards the light, but he seemed to dislike the light and closed his eyes tightly. He refused to let anyone touch him and refused all food. The friends asked me to take him into the hospital as they could do nothing with him. I did so and in the afternoon I saw the patient in the ward. He again refused to let me examine him and became so violent that I had to put him in a special ward and give him an injection of hyoscine. He became quiet, and after four hours' rest he took some food. I noticed that the jaundice was increasing; there was no vomiting, however, so no medicine was given to him. When the nurse left the room for a minute the man got up off the bed and passed his urine on the floor, although there was a urinal in the corner. During the night the man became very noisy and the resident physician was called and gave him another injection of hyoscine. This acted for some four hours and when dawn came the man became quiet. This quietness was the onset of coma, for as the day passed the patient fell into a light sleep, and when his friends came to see him, though he could be roused, he did not recognise anybody. As the man was now lying on his back I made a very careful percussion of the region of the liver. This gave the following results. Dulness below as far the costal margin, upwards as far as the eighth rib in the nipple line, and in the axillary line as far as the seventh intercostal space. The diminution was very marked. The man's friends refused to let him stay in hospital; so I was compelled to let them take the patient out, although his condition was critical. I heard next day that the man died in coma early that morning. I at once sent my assistant to ask if the friends would allow a small post-mortem examination to be made, but they refused.

From the foregoing short account of this curious case it will be evident that it was not a typical one of simple catarrhal jaundice. My reasons for thinking it was one of acute yellow atrophy of the liver are: the very rapid termination of the case in coma; the rapid diminution of the size of the liver; the early onset of delirium, this coming on after only ten days' illness; and the presence of leucin and tyrosin in the urine, although Osler says this is not an invariable symptom. The symptom of vomiting was not a very marked one and soon yielded to treatment. There was no constipation; the original purge that the man took seems to have kept the bowel moving.

Curiously enough, my colleague here, Dr. E. Cuffey, came to me some few days after my patient had died and told me of a very similar case to mine that he had had in his private work here. So similar was it that I thought he was describing my own case, but as his patient died some days after mine there can be no doubt that there have been two cases of what we suppose to have been acute yellow atrophy of the liver in this town within a few days of each other.

The rarity of these cases must be my excuse for sending you this record.

Government Hospital, Port Said, Egypt.

A PRELIMINARY NOTE ON A NEW SPIROCHÆTA FOUND IN A MOUSE.

By ANTON BREINL, M.D.,
ASSISTANT LECTURER, LIVERPOOL SCHOOL OF TROPICAL MEDICINE;
AND
ALLAN KINGHORN, M.B. TORONTO,
JOHNSTON COLONIAL FELLOW, UNIVERSITY OF LIVERPOOL.

(From the Runcorn Research Laboratories of the Liverpool School of Tropical Medicine.)

THE spirochæta described below was found in the blood of a white mouse infected with *Trypanosoma dimorphon*, which was sent from Paris by Professor Laveran, and we take this opportunity of expressing to him our sincere thanks for permission to publish these observations.

In the fresh, the spirochæta imparts a movement to the red blood cells similar to that found in the case of other spirochætæ. The parasite is very small, translucent, and actively motile, and shows both a movement of the spiral turns and a progressive movement of the whole organism between the blood cells. It stains readily with any of the aniline dyes and all the modifications of Romanowski and then appears as a short, plump, uniformly-stained spirochæta. Long and short forms occur, measuring between 1·8 and 3·75μ in length and 0·1 and 0·2μ in breadth. The number of spirals varies between two and four and there is also a variation in the size of the spirals in different parasites. Both ends are drawn out to a point, one usually more abruptly than the other.

The parasites were very scanty. In the fresh, only one or two were seen in a preparation, while in the stained one spirochæta in from 20 to 40 fields (Zeiss, oc. 4, $\frac{1}{12}$ oil immersion) was counted. Attempts to transmit the spirochæta to other mice have been unsuccessful so far.

We have been unable to find in the literature any reference to a spirochæta of mice. Vandyke Carter[1] describes a spirochæta observed in an Indian rat but this is longer and possesses more spiral turns than the one described above. As this appears to be a distinct species, we propose for it the name "*Spirochæta Laverani*" (*n. sp*).

Note.—Since writing the above, a spirochæta of identical appearance with the one described has been found in the blood of a wild mouse, *Mus musculus*. Transmission experiments with this parasite are now in progress.

A CASE OF INTUSSUSCEPTION, ILLUSTRATING THE FALLACIES AND DANGERS OF THE "INFLATION" TREATMENT.

By J. L. FALCONER, M.B., CH.B. VICT.,
RESIDENT MEDICAL OFFICER, MANCHESTER CHILDREN'S HOSPITAL, PENDLEBURY.

A MALE child, aged ten months, was admitted to the Manchester Children's Hospital, Pendlebury, on the evening of Dec. 1st, 1905, under the care of Mr. E. D. Telford, to whom I am indebted for permission to publish the case. The previous history, furnished by the medical man who attended the case outside, was as follows. On Nov. 15th the child started screaming and bearing down and passed about half an ounce of pure blood. On examination per rectum the finger returned covered with blood. No tumour was felt and nothing was recognised on abdominal examination. Blood stained mucus was passed on the next day and on the 17th a tumour was felt per rectum. The child was anæsthetised and the bowel was inflated with water from an elevation of two feet. The tumour moved rapidly up the left side of the abdomen and apparently disappeared. The child was rather collapsed after the operation but soon recovered and passed natural stools. Improvement was maintained till the 21st when the child was noticed to be straining and passing mucus. On examination the intussusception was again felt at the anus. The treatment by water inflation was repeated and the intussusception was apparently reduced. The child continued well next day, but on the 23rd the tumour was again felt in the rectum and water inflation was again resorted to. After this the child continued well until the 29th, passing motions with more or less mucus in them. On this day a mass was felt in the left hypochondriac region, although nothing could be felt per rectum, but on the 30th it was again felt per rectum. The abdomen was distended and the child was developing a typical abdominal facies. On Dec. 1st the patient entered Mr. Telford's wards.

On admission the child was found to be very quiet and lethargic, making no resistance to examination. He looked ill, with very sunken eyes surrounded by dark rings, presenting a marked "abdominal facies." The abdomen was slightly distended and tympanitic on percussion but moved fairly well with the respirations. The recti were somewhat resistant but there was no evidence of tenderness on palpation. No mass could be felt through the abdomen, nor was there any vomiting. The child had a normal stool soon after admission. Examination per rectum revealed moveable gut, with the ileo-cæcal valve forming a tight ring at the apex of the intussusception; the whole mass could be freely pushed away by the examining finger. No blood was seen on the finger after withdrawal.

The following operation was performed by Mr. Telford one hour after admission. The abdomen was opened by a three inch incision through the right rectus muscle; a mass was found low down in the pelvis and at first the invaginated gut was withdrawn fairly easily but soon a portion was reached where the intussusceptum had sloughed right through the intussuscipiens and was surrounded by a localised peritoneal abscess. The mass was then rapidly cut away and the divided ends of the bowel were fixed together in the upper angle of the wound; a rubber drainage-tube was inserted down to the collection of pus and the remainder of the incision was closed.

No cause was found for the origin of the intussusception, which was of the ileo-cæcal variety. Considerable shock was present after operation but this was partly recovered from under strychnine, ether, and saline infusions. The child, however, again collapsed somewhat suddenly and died 10 hours later.

Comments by MR. TELFORD.—The case illustrates the very unsatisfactory nature of inflation treatment; such treatment should be discarded for the following reasons:—

1. *Danger of perforation.*—This may occur early when too much fluid is used or later when a plastic peritonitis has ensued. The constricted and sloughing gut may ulcerate into the general peritoneal cavity if operation is delayed. Inflation at this stage materially increases the risk of rupture of the gut.
2. *Uncertainty of the method.*—The case reported shows well how an apparently satisfactory result at the moment may be quite misleading; probably the last inch of the intussusception is never reduced, as this portion always gives difficulty even on laparotomy when the gut is in the surgeon's fingers.
3. It obviously can be of no use in any variety beyond the ileo-cæcal; the ileo-colic and enteric forms cannot be affected by it.
4. It cannot succeed when plastic peritonitis has ensued and therefore can be of use (if at all) only in the very early stages.

The treatment by inflation is to be condemned on the above grounds; also because it wastes most valuable time and seriously imperils the prospect of a subsequent laparotomy with manual reduction which is the only reasonable treatment. It may be stated that when an acute intussusception has existed for 30 hours recovery after any line of treatment whatever is very unusual and therefore the patient in every case should be subjected to rational and scientific surgery without delay.

Pendlebury.

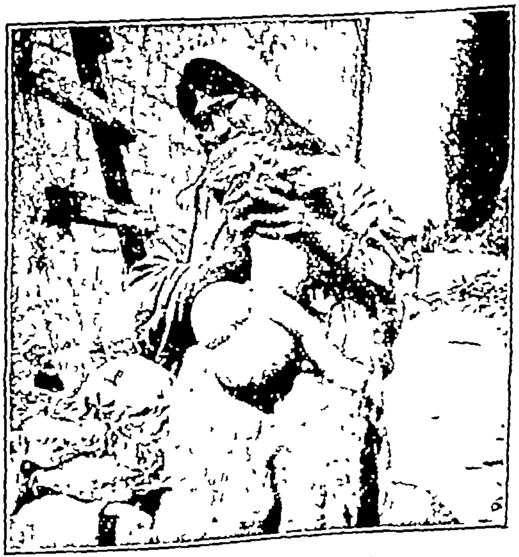
Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SUCCESSFUL REMOVAL OF A LARGE HYGROMA IN A CHILD AGED THREE WEEKS.

By J. CROPPER, M.A., M.D. CANTAB.

IN June, 1905, I was consulted by a Moslem woman about her child, aged three weeks, who had a very large hygroma of the sacral region, of which I inclose a photograph. As the nature of the growth was not certain, and as the skin over it was reddened and threatened to slough, Dr. P.



Appearance of child before operation.

---

[1] Vandyke Carter: Note on the Occurrence of a Minute Blood Spirillum in an Indian Rat. Scientific Memoirs by Medical Officers of the Army of India, Part III., 1687, p. 45.

Wheeler, of the English Hospital in Jerusalem, agreed to admit the child for operation. An exploratory puncture revealed a thick, brownish fluid and hygroma was diagnosed. Having fully explained the risks of leaving the growth as it was and also of operation, the friends made all preparations for the funeral, having before this made up their minds that the child could not survive in any case. After some days in hospital I removed the growth under chloroform by two elliptical incisions, leaving abundant flaps. The contained fluid measured over three pints. The need for speed was quite as great as in pre-chloroform days, for though the loss of blood was not great there was sudden collapse from which, however, the patient rallied. The size of the incision may be judged from the illustration; it extended downwards to the anus. The edges were quickly brought together by sutures, few vessels needing ligature. The lower end of the wound healed by first intention, the upper part oozed for some time, but at no time was there any serious rise of temperature. A minute sinus remained for a while after this. No attempt was made, of course, to remove the hygromatous mass firmly adherent to the sacrum. When seen ten months later the child was doing well so far as the operation went, but was considerably pulled down by fever and had an enlarged spleen. It would, of course, be possible at a later date to produce a more "cosmetic" effect. I have to thank Dr. Wheeler for admitting the child and for his help at the operation.

Ramallah, Jerusalem.

RECOVERY AFTER TAKING OVER 40 GRAINS OF PERCHLORIDE OF MERCURY.

By PELHAM C. MAITLAND, M.R.C.S. ENG., L.R.C.P. LOND.

IN answer to a hasty summons from a much perturbed husband to come at once to see his wife, who had swallowed some poisonous tabloids, I found she had dissolved five tabloids of hydrargyri perchloridum in a cup of water and drank the whole. This would amount to 43¾ grains, each tabloid containing 8·75 grains. This, from searching inquiries and questionings, I have not the slightest reason to doubt was true. I took away the cup with the drainings and found after testing with iodide of potassium a plentiful precipitate of biniodide of mercury. They were the ordinary tabloids, given by another medical man for injection. I found the woman very ill, quite prostrate, vomiting, with abundant diarrhœa. At once, after finding out the nature of the case, I gave about four ounces of carron oil made with oleum morrhuæ as the only oil available quickly. This I followed with one ounce of vinum ipecacuanhæ. I then dispatched the husband for eggs and milk. These being obtained after a time, the whites and milk were given. As there was such a large quantity of the poison I feared the after effects and gave rather a bad prognosis. I was compelled by engagements to leave the case, but I told the husband what to do, and if necessary, or in certain circumstances, as severe prostration, to call in another medical man, as I could not return that night. On the next morning I found the patient—in spite of some pain and prostration, due partly to the remedies employed—comparatively convalescent. In a day or two, with bismuth and tinctura opii and emollient feeding, she quite recovered.

Shepherd Market, Mayfair, W.

NOTE ON A CASE OF BRADYCARDIA.

By CHARLES EDMUND MCDADE, M.D. R.U.I., D.P.H.

THE following note on a case of bradycardia unattended with any manifest disease and ending in recovery may prove interesting.

The patient was a man, aged 72 years, who had led a very active life as a public speaker. His health had been good until recently and his family history was also good, with longevity on the maternal side. In July, 1904, he complained of slight giddiness, which yielded to soda, nux vomica, and carminatives. His pulse was then 65 per minute, strong, and regular; his tongue was clean, his appetite was good, and his bowels were regular. The following February he had the same trouble, which soon passed off with the same treatment. On June 2nd I saw him again. His pulse was now 40 per minute, but strong and quite regular. He could speak in public as usual, but any physical exertion required an effort quite unusual to him. In walking he felt that he must stop at times although his breathing was not at all affected. The heart sounds were clear, the blood-vessels seemed healthy, and the urine was normal. He continued his work as usual, walking as little as possible. On June 23rd his pulse was 78 per minute, strong, and regular. On July 7th the pulse had again fallen to 40 and was so on the 14th, when he had to leave home to preside over a large religious congress which involved continuous public work from day to day for three weeks. He performed all this without any great fatigue. I saw him again on August 13th when his pulse was 64, strong, and regular and he felt well except that he did not care for walking. For the following three months he was very fully occupied, speaking in public from six to 12 times each week and travelling all over England. I saw him again on Nov. 13th. His pulse-rate was then 38. He looked tired but still persisted in his work which was all planned beforehand.

From this time until Dec. 15th I saw him each week on his return home; he appeared to be gradually failing, his pulse falling to 32 per minute, but still strong and regular. On this date he had a sharp attack of diarrhœa during which the pulse became intermittent and varied in rate from 32 to 40. From Dec. 19th he stayed in bed, and after a few days' rest his condition was as follows. The radial pulse was regular with a rate of 28 per minute, while the jugular pulsation was 56. At the apex the heart could be heard beating in exact unison with the pulse at the wrist. About one inch nearer the middle line a faint sound could be heard exactly half way in time between each sound at the apex, as if the right ventricle contracted twice as frequently as the left. No intermediate pulmonary second sound could be heard. The breathing was quite normal and there was no cyanosis. The tongue was clean and the bowels were regular. The abdomen was rather tense, giving a tympanitic note as high as the fourth rib on the left side. This flatulent condition disappeared in a fortnight when treated with sulphocarbolate of soda and carminatives.

For the next four weeks he was kept in bed and fed on light nutritious diet. His radial pulse-rate varied from 27 to 32, but was always strong and regular, while the intermediate sounds heard internal to the apex gradually became more perceptible, and the jugular pulsations were, always just twice the radial pulse-rate. On Jan. 25th, 1906, the urine was loaded with urates and gave a slight haze on boiling. On Feb. 1st the radial pule-rate was 32, and the pulmonary second sound could now be heard 64 times a minute, the intermediate sound being weaker than the sound which was synchronous with the apex beat. The left ventricle was beating 32 times a minute. On the 4th the intermediate sounds were more pronounced. On the 5th the radial pulse was 63 per minute, strong, and regular. For the next four weeks it varied from 48 to 80, only reverting to the condition of bradycardia on one occasion after a sharp attack of diarrhœa.

During February there were several attacks of diarrhœa which were accompanied with a suppression of one beat in seven at the wrist. On two occasions there were two beats missed at the wrist in succession and the patient's head gave a momentary nod each time it did so. A few days after the pulse rate was restored he complained of a continuous pain on the left side of his head; this eased off when the pulse-rate *fell* below 65 but was very bad when the pulse-rate was over 75. When the pain was severe the anterior branch of the left temporal artery felt hard like whipcord, the right side being quite normal. This pain persisted more or less for about a fortnight. The urine was still full of urates and gave a haze on boiling. He was now able to get up each day, his strength returning very slowly. From March 1st the pulse ceased to be intermittent. On March 30th he was sufficiently recovered to leave home for the seaside and resumed his public work on April 23rd. On April 29th his pulse was 72, every beat strong and regular, and he felt fairly well. Sir William Broadbent saw him with me on Dec. 28th, 1905, and March 21st, 1906.

CLAYTON HOSPITAL, WAKEFIELD.

A CASE OF PUERPERAL FEVER SUCCESSFULLY TREATED WITH ANTISTREPTOCOCCIC SERUM.

(Under the care of Mr. WILLIAM STANGER.)

FOR the notes of this case we are indebted to Dr. C. Dyson Holdsworth, house surgeon to the hospital.

The patient, who was aged 23 years and had already given birth to one child, was delivered of a male child on Oct. 19th, 1905. The midwife in attendance was unable to deliver the placenta. After the lapse of nearly two hours, during which time there had been considerable hæmorrhage, Mr. L. T. Wells was called in. He had to strip off the placenta manually but it came away whole. The first week of the puerperium was normal but on the night of the 26th the patient's temperature ran up to 105°F. and the lochia became foul. Vaginal douches containing perchloride of mercury were given, cold sponging was practised, and quinine was administered in an effervescing mixture. On the next night the patient's temperature again rose to 105°, but after this there was a slight improvement which, however, proved to be only temporary, so she was removed to the Clayton Hospital on Nov. 6th. As her temperature remained irregular and the discharge began to increase the uterus was explored under an anæsthetic on the 8th and some fragments of membrane were removed with a blunt curette. Intra-uterine douches were given daily for the next week, the discharge decreasing rapidly. On the 9th a pyæmic abscess was opened in the left deltoid region and numerous streptococci were found on microscopical examination of the pus. That evening 20 cubic centimetres of antistreptococcic serum were injected into the abdominal muscles. At midnight the temperature had risen to 105° and the pulse-rate to 150, so ten more cubic centimetres of serum were given. On the following morning the temperature had fallen to 100° but about 7 P.M. the patient had a rigor and her temperature ran up to 105·6°, with a pulse-rate of 138; ten cubic centimetres of serum were administered and as her condition was apparently becoming worse 20 more cubic centimetres were injected and liquor strychninæ hydrochloridi was given every four hours in five-minim doses hypodermically. During the next two days 30 cubic centimetres of serum were given per diem but the patient seemed to be sinking. Several pyæmic abscesses were opened—namely, one in the lumbar region posteriorly, another in the right arm, and another in one of the fingers of the left hand. She then rallied slightly and on the 15th her temperature was down to 99°, so the serum, which had been used in 20 cubic centimetre doses for the last three days, was discontinued. The improvement lasted until the night of the 20th, when the temperature rose to 103° and the serum treatment was accordingly resumed, 20 cubic centimetres being given per diem. On the 23rd the temperature rose to 104·4° and the pulse-rate to 144, so the serum was increased to 30 cubic centimetres per 24 hours for the next three days.

On the 25th a large amount of pus was evacuated from the back. The patient seemed to be becoming feebler and her pulse weaker, so digitalis was administered instead of strychnine for a few days with apparent benefit. On the 26th, as the temperature was lower and the patient seemed a little better, the serum was discontinued; on Dec. 3rd, however, the temperature rose to 103°, so ten cubic centimetres of serum were given on this and the succeeding day, after which no more serum was used. For the next three weeks the patient's temperature remained irregular and several new abscesses had to be opened. The temperature then became steadier, the abscesses gradually dried up, and with the help of tonics the patient made a very good recovery. For a time there was some stiffness of the joints but this was gradually overcome by massage and the patient was able to leave hospital on March 31st. Owing to the difficulty in obtaining supplies three brands of serum were used, the respective makers being Parke, Davis and Co., Burroughs, Wellcome and Co., and the Lister Institute. The temperature and general condition always seemed to respond to the serum and no unpleasant effects were manifested at the sites of injection. During the greater part of the febrile portion of the illness small doses of quinine were given in an effervescing mixture.

BUDLEIGH-SALTERTON COTTAGE HOSPITAL.

A CASE OF RUPTURED PYOSALPINX COMPLICATED BY A LARGE OVARIAN CYST.

(Under the care of Mr. THOMAS G. C. EVANS and Mr. RUSSELL COOMBE.)

THE patient was 39 years of age and had been married for ten years but had never been pregnant. Eight weeks after marriage she had an attack of pelvic pain which kept her in bed for six weeks. During the last few years she had had frequent attacks of abdominal pain which had kept her in bed for a few days at a time. One of these lasted from Feb. 13th to 16th, 1905, and about midnight between Feb. 16th and 17th she had an attack of very acute pelvic pain with vomiting and repeated shivering fits. She was seen by Mr. Evans on the morning of the 17th. Her pulse-rate was then from 150 to 160 and her temperature was 105° F. Her abdomen was distended and very tender just above the pubes. She was removed to the hospital.

Mr. Russell Coombe saw her with Mr. Evans at 3 P.M. Her abdomen was distended and moving fairly freely; both flanks were resonant; the central part of the abdomen from the pubes to above the umbilicus was dull; there was exquisite tenderness on the left side above the middle of Poupart's ligament; the pulse-rate was 160 and the temperature was 103°. Chloroform having been administered by Dr. A. Walker, and Mr. Evans assisting, Mr. Coombe made an incision through the left rectus when a large ovarian cyst, not congested, presented. The excision was extended and this was delivered. It was found to be incorporated with the right side of the womb and the right tube, splitting the broad ligament and lifting the peritoneum up to the pubes anteriorly and up to the cæcum on the right side, so that the bladder showed in a groove on its left side below and the appendix in a groove on its right side above. All attempts to clear it from its connexion with the peritoneum and broad ligament failed and it was therefore drawn over against the right side of the abdominal wound. The pelvis was then explored and the left tube was found to be much enlarged and surrounded by pus which was escaping from a hole in the tube; the pus was sponged up, the tube was emptied, and the tear was clamped. The tube was then dissected off three or four inches of bowel to which it was adherent, the raw surface was covered, and the tube was ligatured off close to the uterus and removed. The remainder of the ovarian cyst was narrowed by a purse-string suture and cut off flush with the abdominal wound, its cavity was packed with gauze, and it was fastened in the lower end of the wound. A large drainage-tube with a gauze wick was then passed down to the stump of the left tube and the abdominal wound was closed with silkworm-gut sutures. The patient made an uninterrupted recovery and is now (August, 1906) in excellent health.

THE WINSLEY SANATORIUM.—The trustees of the Winsley Sanatorium have convened a meeting to consider the financial position of the institution and a proposition which has been made to enable them to raise £7500 on mortgage.

INTERNATIONAL CONFERENCE ON TUBERCULOSIS.—The International Central Bureau for the Prevention of Consumption is meeting at the Hague this week, the deliberations commencing on Sept. 5th. The National Association of England is represented by Dr. C. Theodore Williams and Dr. Nathan Raw.

Reviews and Notices of Books.

Arbeiten aus dem königlichen Institut für Experimentelle Therapie zu Frankfurt-a-M. Herausgegeben von Geheim Medecin Rath Professor Dr. P. EHRLICH. Heft I., mit 6 Tafeln. Jena: Gustav Fischer. 1906. Pp. 102. Price 9*s.*

Professor Ehrlich has reprinted and expanded several papers on cancer in mice which have been published by himself and Dr. H. Apolant since July of last year. To these papers he has contributed a preface in which he summarises the general scope of his investigations. Sticker's observations in dogs on what Ehrlich maintains is a lympho-sarcoma are referred to, as are also those of Sticker and Marx on *molluscum contagiosum*, both having been made in Ehrlich's Institute. The inclusions in cancer cells, such as those so carefully investigated by Plimmer and bearing his name, have been carefully studied and they are stated to be non-parasitic in nature. Ehrlich asserts that no success has yet attended the attempts to solve the problem of cancer by purely histological or purely experimental methods, nor has the study of the processes of division in cancer cells had any useful result. All practical medical men will be in agreement with Ehrlich if his view is that until cancer can be *produced de novo* experimentally we are reduced to studying the behaviour (growth) of fully developed cancer. He lays weight on the fact that he has been able to study 250 tumours in mice and believes that this large number enables him to draw conclusions more certainly than Bashford could do "from a much smaller number of cases."

So much for the preface, the volume itself consists of three parts. In the first part Dr. Apolant discusses the histological features of the mammary tumours of the mouse and the general results of attempting to transplant them; in the second, Ehrlich describes a transplantable chondroma; and in the third he summarises his experimental studies and puts forward some suggestive speculations. Dr. Apolant examined 221 mouse tumours, which he correctly regards as epithelial tumours of the mamma; metastases were present in only six. The tumours he classifies in sub-groups according to their histological characters, represented at one end of the scale by simple adenoma and at the other end by alveolar carcinoma. The histology of the different groups is illustrated on three plates. According to the author, the adenomata are frequently transformed into carcinomata and the process of transformation can be distinctly followed, proceeding either diffusely or in circumscribed areas. An increased energy of growth on the part of the mammary tissue itself may result in the direct development of carcinoma without an intermediate adenomatous stage.

The transplantation of the tumours has been attempted in the following manner, and it is characteristic of the advantageous conditions under which medical research is pursued in Germany that Ehrlich was able to delegate the routine work of many thousand inoculations to skilful laboratory servants. The tumour has been broken down in a mortar to the consistence of an emulsion and a small quantity of this injected subcutaneously. Two days after, the mass is for the most part necrotic and inclosed within a thin zone of proliferating cells. The author gives scant notice to the respective parts played by parenchyma and stroma, possibly because of the difficulty of doing so in broken-down tumour tissue. He contents himself with stating that the tumours develop from isolated groups of cancer cells. It is unfortunate that the part of the stroma is not alluded to, for the author describes the development of growths with the histology of a spindle celled sarcoma in the course of the continued propagation of two of the carcinomata. Apolant found macroscopic metastases in the lungs in the course of the propagation of only one sporadic tumour, and this is explained by Ehrlich as due to the rate and amount of the growth at the site of inoculation starving, as it were, any cells which might have given rise to metastases. Apolant emphasises the absence of infiltrative growth both in the primary and in the transplanted tumours, and in doing so seems to us rather to ignore the demonstration given last year in the reports of the Cancer Research Fund that "expansive" and "infiltrative" growths are dependent on the varying resistance of the tissues to the growth of experimental tumours.

In the third paper Ehrlich reviews the results of his experiments from the standpoint of the "side-chain" theory of immunity, or more concretely from the standpoint of the mechanism of assimilation which the theory postulates as an explanation of the taking up of foodstuffs by cells. The difficulty attending the primary inoculation of spontaneous tumours of the mouse is referred to (Ehrlich only succeeded in transplanting 14 tumours out of 94) and is compared to the varying suitability of animals for grafting of normal tissues, especially embryonic. He concludes that normal animals must possess powers which prevent the continued growth of the tumour cells. In consequence the spontaneous development of cancer is supposed to depend on *two factors*: (1) the primary cancerous cell transformation and (2) the growth of this small cancerous area into a tumour. As is now generally recognised, the two factors are quite independent, and Ehrlich contrasts them as presenting an analogy with (1) the introduction of the tubercle bacillus and (2) the development of progressive tuberculous lesions. The possibility of varying virulence of the cancer cells playing an important rôle, just as in the case of tubercle, is treated as of subsidiary importance, and all carcinomata are apparently regarded as potentially equally virulent, although the divergent results of the primary transplantations recorded in the papers seem directly to negative such a conclusion. Ehrlich strongly holds that it is possible to increase artificially the power of growth of the cells by selective transplantation and in this way to overcome the individual resistance. The frequency of spontaneous cancer is believed to be determined by the absence of this natural power of resistance.

The results of transplanting mouse tumours, especially the sarcomata already referred to, in rats are described in this section at some length. A temporary proliferation is obtained in the rat; after a week the tumour ceases growing and is ultimately absorbed. This result is made the basis of a fundamental speculation on the bio-chemical conditions under which the growth of tumour cells proceeds. In addition to the ordinary foodstuffs necessary for growth, and which are supplied equally by the rat and by the mouse, Ehrlich postulates a special substance "x" necessary for continued growth and found only in the mouse. The amount of this substance "x" transplanted along with the tumour cells suffices to enable the cells to grow for a time in the rat, and when this amount is exhausted growth ceases. The immunity of the rat to a mouse tumour is hence not due to inimical substances in the rat's body but to the absence of the substance "x" necessary for growth; the immunity is due to "atrepsie" (from τρέφω—nourish). In a similar manner Ehrlich accounts for the small size of the lung metastases he has observed in mice with transplanted cancer, and ignores, or is unaware of, the large size of the metastases which other investigators have observed. The primary tumour requires so much of the special foodstuffs ("x," &c.), according to Ehrlich, that the metastasis is starved. Pursuing this line of reasoning, the conclusion is arrived at that the absence or the small size of metastases is evidence of a special kind of malignancy, characterised by an abnormally high power of proliferation. The relative energy with which nourishment is taken up by the tumour cells and the body cells respectively is made the subject of an interesting speculation. Briefly, Ehrlich, it seems to us, assumes that a tumour which does not grow on transplantation fails so to do because the avidity of the cells of normal animals for nourishment is greater than that of the tumour cells in question. *A fortiori* the tissue cells of the animal spontaneously suffering from such a tumour must have had an avidity much below normal and this constitutional dyscrasia determined the growth of the tumour in that animal; in other words, was the cause of cancer. It is suggested that such a diminishing power of absorbing nourishment on the part of the tissues generally as age advances may account for the age-incidence of cancer.

The papers are a valuable contribution to the experimental study of cancer. Many of the facts are identical with those on the growth of cancer under experimental conditions with which the work of the Cancer Research Fund has made us familiar in this country during the past three years. The results of the German and English investigations, where they cover the same ground, are for the most part confirmatory of one another, and where they do not overlap they are complementary of one another. The speculations in which the distinguished German investigator indulges are characteristic examples of Ehrlich's scientific use of the imagination. Speculation on the nature of cancer knows no limits, and in this connexion we may add that Professor Ehrlich is not always urbane in his allusions to the work, some of which is necessarily speculative, of other observers.

Gynæcological Diagnosis. By ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin., M.R.C.P. Lond. With 35 original illustrations. London: Baillière, Tindall, and Cox. 1906. Pp. 212. Price 7*s.* 6*d.* net.

Dr. Giles truly points out in his introductory chapter that there are many difficulties in the way of the student who is anxious to obtain some practical knowledge of gynæcological diagnosis. Only too often his opportunities of making pelvic examinations during his student career are of the scantiest, and unless he holds some resident post he may well commence practice without being able to say with certainty what the exact condition of the pelvic organs in any given case may be. A book such as this will prove of considerable assistance to the student in helping him to make the most of his scanty opportunities, and will also be of assistance to those who are engaged in teaching students this branch of medicine. It is written purely from the clinical point of view and on the plan of arriving at a diagnosis from the presence of certain symptoms or physical signs. The various symptoms are discussed in turn and the different conditions which may be associated with them are pointed out. At the end of most of the chapters synoptical tables are given, showing in a clear form what pathological states are met with in association with certain groups of symptoms and physical signs. In this way practically the whole field of gynæcological diagnosis is covered.

Dr. Giles has carried out his purpose fairly well. We are surprised, however, to find no mention of what may be termed ordinary ovarian pain either in the text or in the index. Apparently the author holds that all cases of such pain are due to a condition of so-called oöphoritis. This we cannot agree with and we are not aware of any proof of such a view. Cervix-adenoma is a term which we think might well be given up. An erosion is in no sense of the word a true adenoma, and the use of this term only leads the student to imagine that it is some form of new growth resembling the common adenoma of the breast with which he is probably best acquainted. To call an erosion of the cervix uteri an adenoma seems to us a misuse of a term which has always had a well-recognised meaning. On p. 126 we are told in the diagnosis of the causes of hæmorrhage from the body of the uterus that we may feel a mass with the consistency of adenomata. We do not quite know what the author means, but are sure that statements of the kind are out of place in a book for students. Indeed, throughout a book which displays much industry and knowledge the author is not sufficiently careful to weigh his words exactly. One of the most difficult abdominal tumours to diagnose correctly is an encysted collection of fluid due to tuberculous disease of the peritoneum. We are afraid that but little assistance would be obtained by anyone referring to Dr. Giles's book for help in the recognition of the condition. Again, it is not very accurate to say that the hymen is deficient in pregnancy, when what is meant is that the hymen is torn or stretched. It would be difficult for anyone to make a correct diagnosis of hydramnios on the very insufficient data which are given. A large abdomen occupied by a smooth tense tumour in which fœtal parts can be made out appearing to correspond to one fœtus only, and in which only one fœtal heart can be heard, does not seem to us either a correct or an adequate description of a condition which is not uncommon and which often leads to difficulties in diagnosis.

One of the chief difficulties in writing a book purporting to supply a synoptical scheme of diagnosis is to insure that all the symptoms of any given disease shall receive a place. Thus in the present instance there is no mention of the abdominal pain so constantly present; nothing is said of chills or fever, or of the pain on micturition commonly met with in these cases. Dr. Giles may have been afraid of seeming to repeat himself, but in a book for students such repetition is often a virtue.

We have frankly pointed out what we consider the defects and omissions in a book with many good qualities, but no doubt in a future edition the author will amplify and improve his work, when it should be found a very useful one. The illustrations are clear and useful.

Acute Contagious Diseases. By WILLIAM M. WELCH, M.D., and JAY F. SCHAMBERG, A.B., M.D. Illustrated with 109 engravings and 61 full-page plates. London: Henry Kimpton. 1905. Pp. 781. Price 25*s.*

THE authors in their preface explain that the diseases dealt with are those of which they have had special experience in the municipal hospital at Philadelphia and that they have dealt with those especially characterised by transmissibility and by contagion rather than the group of "infectious diseases" as a whole which would have necessitated the inclusion of maladies upon which they do not feel specially qualified to write. The text is based upon, among other things, a personal study of over 9000 cases of small-pox, 9000 cases of scarlet fever, and 10,000 cases of diphtheria, which no doubt accounts for the fact that the authors are eminently practical in their descriptions of the diseases of which they write. One of the most noteworthy features of the book is the excellence of the illustrations which are almost without exception good reproductions of photographs of actual cases. The various rashes are represented by typical examples and in some cases serial photographs of the course of the rash are given. Specially worthy of mention is the series of eight full-page plates showing the course of the rash in small-pox in an unvaccinated man, from the appearance of the papules to the stage of scarring. Many of the other rashes are also shown as well as possible without coloured plates.

The book begins with an exhaustive study of vaccinia, which though not strictly a contagious disease within the definition of the authors, is included because of its relation to variola. The history of vaccination is given in considerable detail; the technique of the process, the course of the disease, its complications and sequelæ are carefully described, and a section is devoted to statistical evidence of the value of vaccination which is well worth study. An interesting chapter deals with the variolous diseases of lower animals and contains a good deal of information with reference to the literature of this comparatively neglected study. Chapters IV. and V., comprising together 172 pages, are devoted to variola and constitute a thoroughly comprehensive study of that disease copiously illustrated from the authors' own extensive experience. The account of the diagnosis and treatment is thoroughly practical and useful. The Cytorextes variolæ is carefully described and references are given to the literature of the subject. Chicken-pox is next dealt with and the symptoms, diagnosis, and complications are carefully given. The account as a whole is perhaps a little less exhaustive than that given of variola. Scarlet fever is next discussed and the account given is of equal merit with those preceding it. The illustrations of the process of desquamation are particularly good and should be useful to the student or practitioner using the book as a a work of reference. The account given of scarlatinal rheumatism is shorter and less complete than we should have looked for in a work of this magnitude. In the section devoted to measles some coloured figures are given, reproduced from Koplik, of the spots which are usually referred to by his name. This chapter is nearly as lavishly illustrated by reproductions from photographs as that on variola. Rubella is next considered and its various forms are described and illustrated.

Typhus fever and diphtheria complete the list of diseases comprised in the contents of the volume. The article on typhus fever contains far fewer references and is shorter than most of the others, but the general features of the disease and its complications are adequately described. The diagnosis of this disease, now fortunately so comparatively uncommon in most parts of this country, is carefully considered. The account given of diphtheria includes the bacteriology of the disease, its various forms, and their recognition and prognosis. The serum treatment is dealt with in a chapter to itself where statistics of its effects are given. The authors give as their experience that cases treated by medium-sized doses recover as well as those receiving very large doses, after the manner recommended by McCollom of the Boston City Hospital. The various antitoxin rashes are described and figured. The book concludes with a short chapter on disinfection, which might with advantage have been extended so as to include some general remarks on quarantine, for quarantine is only referred to in the chapters on scarlet fever and variola.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXIV., Nos. 4 and 5. Cambridge University Press: C. F. Clay. August 10th, 1906. Price 8*s.*—The articles contained in this number of the journal are: 1. The Regeneration of Post ganglionic Vaso-constrictor Nerves, Part I., by Basil Kilvington and W. A. Osborne, with nine figures in the text. Starting from the observation of Langley and Anderson that when the central end of a divided limb nerve has an opportunity of joining with two peripheral nerves stimulation of one peripheral nerve, after complete severance of the conjoined nerves from the central nervous system, may cause contraction of the muscles innervated by the other, the author draw the conclusion from their experiments that when the central end of any nerve distributed to a limb is sutured to the ends of two peripheral nerves, vaso-constrictor fibres can be detected after a time in both peripheral nerves, but no axon bifurcation of vaso-constrictor fibres takes place. 2. The Post-mortem Flow of Lymph, by F. A. Bainbridge. The experiments were made on dogs and the flow of lymph from the thoracic duct was usually observed to continue for about an hour after death and was most abundant during the first 20 minutes. It is chiefly derived from the liver capillaries, from whence it is squeezed into the thoracic duct by intestinal movements taking place after death. 3. The Influence of Organ Extracts of Cold-blooded Animals on the Blood Pressure of Dogs, by Orville Harry Brown, M.D., and Don R. Joseph, M.S., with eight figures in the text. The animals experimented on were dogs and the extracts used were those of the liver, kidney, and sex glands of sharks, squeteague, and dog-fish. These contain both pressor and depressor substances, the effects being due to vaso-motor changes. 4. Further Observations upon the Functions of the Thyroid and Parathyroid Glands, by Swale Vincent, Professor of Physiology in the University of Manitoba, Winnipeg, and W. A. Jolly, assistant to the professor of physiology in the University of Edinburgh. In these further observations the authors state that their experiments show that neither thyroids nor parathyroids can be considered organs absolutely essential to life. Many animals suffer but little from their removal. They think that the pathology of myxœdema must be more complex than simple thyroid insufficiency. 5. The Estimation of the Oxygen Dissolved in Salt Solutions, by Joseph Barcroft and Philip Hamill, with three figures in the text. The figures represent the apparatus employed. 6. Experiments in Examination of the "Locked Jaw" Induced by Tetanus Toxin, by Herbert E. Roaf, M.D. Toronto, and C. S. Sherrington, with four figures in the text. Three of the higher types of apes were the subjects of experiment—Cercopithecus, Cynocephalus, and Simia. The changes in the reactions observed seemed to the authors explicable by changes in the condition of lower centres upon which the "motor" cortex acts. 7. Cortex and Medulla in the Suprarenal Glands, by T. R. Elliott (G. H. Lewes student), and Ivor Tuckett. The relative masses of these parts were compared and the effects of the removal of the glands observed. In the guinea-pig removal of both glands causes death in a few hours and the removal of one gland, notwithstanding the exercise of great care, proved fatal within 24 hours. A description is given of the histology of the glands not only in the guinea-pig but in the Monotremata. The effects of suprarenal grafts in the guinea-pig are discussed. 8. Further Observations on the Time Relations in the Action of Trypsin, by S. G. Hedin. 9. On the Optimal Electric Stimuli of Normal and Curarised Muscle, by Keith Lucas, Fellow of Trinity College, Cambridge, with six figures in the text. The Proceedings of the Physiological Society on June 2nd, 1906, are also given.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and SYDNEY HICKSON, F.R.S. With lithographic plates and text figures. London: J. & A. Churchill. August, 1906. New Series, No. 199 (Vol. L., Part 3). Price 10*s.*—The contents of this number are: 1. On the Development of Nebalia, by Margaret Robinson, Zoological Research Laboratory, University College, London. The Nebalidæ form one of the lower subclasses of the crustacea, the body presenting 21 segments, of which the foremost are inclosed in a bivalve shell. Miss Robinson obtained her specimens from Naples, Jersey, and Roscoff. The nearest allies amongst the Entomostraca are, she thinks, the Phyllopoda and she regards it as probable that Nebalia is the most ancient crustacean at present known. Miss Robinson gives the earlier stages of the development and illustrates her description with six plates. 2. On the Early Stages in the Development of Flustrella Hispida (Fabricius) and on the Existence of a Yolk Nucleus in the Egg of this Form, by R. M. Pace (*née* Clark), late scholar of Girton College, with four plates.

The material on which the article is based was obtained from the south coast and Isle of Wight where it is found growing abundantly between tide marks on fucus and other algæ, the colonies forming dark, mossy-looking patches incrusting the algal fronds. The *Flustrella* is a Bryozoan and the reproductive process can be followed from February to August. A yelk nucleus of the type seen in Pholcus is present in the developing egg. Segmentation and cell lineage have been followed out in detail and are illustrated in four plates up to the 32-cell stage. The formation of the endoderm has been traced. The oral and aboral ectoderm are shown to be differentiated as early as the 16 cell stage. The ciliated ring of the larva is formed by the coalescence of several distinct rows of cells and the animal is provided with a stomach. 3. Researches on the Origin and Development of the Epiblastic Trabecula and the Pial Sheath of the Optic Nerve of the Frog, with Illustrations of Variations met with in other Vertebrates and some Observations on the Lymphatics of the Optic Nerve, by J. T. Gradon, M.A., St. John's College, Oxford, with two plates. Mr. Gradon finds that the cells of the optic stalk perform the following three functions. They conduct the nerve fibres, which in their turn resolve the constitution of the cells of the stalk so that they, in the second place, provide the nerve fibres with a supporting framework which, thirdly, provides the whole interior of the optic nerve with an elaborate system of minute lymph channels. 4. Piroplasma Muris, Fant., from the Blood of the White Rat, with Remarks on the Genus Piroplasma, by H. B. Fantham, B.Sc. Lond., Derby Research Scholar, University College, London, with a plate. The parasite was found to be widely distributed through the body of the rats examined, it is intra-corpuscular in habit, occurring in the red corpuscles of the host and belongs to the order Hæmosporidia of the class Sporozoa. They resemble a pear in form and are from 0·5 μ to 1·5 μ in diameter and from 2 μ to 3 μ in length, with usually one chromatin body. They multiply by simple fission.

LIBRARY TABLE.

Anæsthesia in Dental Surgery. By THOMAS D. LUKE, M.B. R.U.I., F.R.C.S. Edin. Second edition. With 29 illustrations. London: Rebman, Limited. Pp. 227. Price 6s.—Dr. Luke has much increased the usefulness of his little book by the additional detail into which he has entered with regard to local anæsthesia for dental extractions. Indeed, we regard the chapter upon this subject as the best and most important in the book, for we are not acquainted with any work on general anæsthetics in which the matter of local anæsthesia in dental work is fully dealt with. Dr. Luke has added an appendix dealing largely with chloroform in dental surgery. Here, while we are in entire agreement with the general principles enunciated, we find some statements as to the action of chloroform which we do not confirm and which are not in accordance with generally accepted doctrine. Dr. Luke appears to us to lay too much stress upon the liability to reflex vagus inhibition in light chloroform anæsthesia and too little upon the importance of dosage. Also one of his explanations of chloroform death as due to "direct retardation and arrest of the pulmonary circulation, first in the capillaries and later in the larger vessels, due to direct local action of chloroform," is a statement for proof of which we should be glad to have reference. Dr. Luke enters upon the question of the administration of anæsthetics by those holding a dental but no medical diploma and draws attention to the looseness of all legal statement in the matter. We think that he might have spoken with even more marked emphasis upon the undesirability of the administrations being conducted by any but a properly qualified medical man and upon the advantages of more medical students making themselves really proficient in dental anæsthetics before going into practice. Dr. Luke's book is clearly written and well produced and we congratulate him upon the need for a second edition.

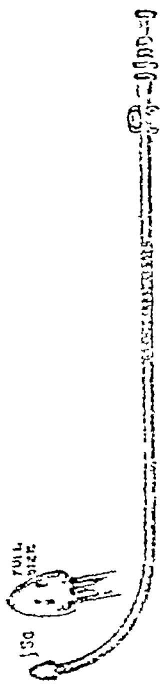
Lehrbuch und Atlas der Zahnärztlichen Technik. Von Dr. Med. und Phil. GUSTAV PREISWERK. With 330 Illustrations. Munich: J. F. Lehmann's Verlag. 1906. Pp. 442. Price 14 marks.—This volume should prove of value to those who are more particularly interested in the mechanical side of dental practice. It is hardly within the scope of this notice to enter into a detailed criticism of the various methods advocated; suffice to say that the different ways of replacing teeth by means of crowns, bridge-work, and ordinary plate-work are fully described and illustrated in a thoroughly up-to-date manner. The final pages of the book are devoted to the methods of making obturators and to regulating appliances. The volume forms one of Messrs. Lehmann's well-known series and should help in sustaining the reputation which that series has already obtained.

Methods of Organic Analysis. By HENRY C. SHERMAN, Ph.D., Adjunct Professor of Analytical Chemistry in Columbia University. New York and London: Macmillan and Co., Limited. 1905. Pp. 245. Price 7s. 6d.—In the words of the preface "no attempt is made to touch upon all important branches of this subject." The principles of organic analysis as applied to food and drink materials are, however, adequately set forth and the particular topics chosen as examples are well calculated to give the careful reader a very good groundwork of organic methods and to put clearly before him the meaning of the results. Apart from this, the author has exercised an excellent discretion in his selection of references to the works on the subject by acknowledged authorities not only in America but in this and other countries. The reader, therefore, who is eager to pursue his studies farther into any given subject or to acquire greater detail is not left without the references to the contributions of special workers which are likely to afford him just the information that he requires. The following are the food products which are analytically discussed in the 14 chapters: alcohols (including glycerine), aldehydes, carbohydrates, acids (including vinegar and fatty acids), oils, fats and waxes, butter, soap and lubricants, proteids and cereals, milk and preservatives. The book sets forth an excellent introductory scheme of training in organic analysis.

THE WANT OF PROPERLY EQUIPPED MORTUARIES.—On Sept. 4th Mr. Troutbeck, coroner for the South-Western District of London, made some observations at Battersea respecting the lack of means for the preservation of bodies. Some of those which his jury had sat upon that day were in an advanced state of decomposition. He remarked that the weather had something to do with this state of affairs but considered none the less that there was pressing need for a better state of things at public mortuaries. The Battersea mortuary was one of the best equipped in London, yet it fell far short in regard to means for preserving the dead. Mr. Troutbeck went on to say that in any similar case where suspicions of poison existed the difficulties of the pathologist and toxicologist would be very great, and he concluded that the existing state of affairs was due to divided authority, one authority appointing the coroner, another providing the court, and another the mortuary. The authorities as at present constituted often did not possess the power to provide that which they ought to provide; there was, for example, no power to provide a toxicological laboratory. It was merely a matter of chance that the authorities were enabled to employ pathologists who had laboratories of their own, otherwise toxicological examination in London would be impossible in connexion with coroners' courts. Having mentioned that in hospitals and in foreign mortuaries corpses were preserved from corruption by proper scientific means Mr. Troutbeck concluded by urging re-arrangement of the law. The jury intimated that they concurred with his views

New Inventions.

A BACK-FLOW CATHETER FOR URETHRAL IRRIGATION.

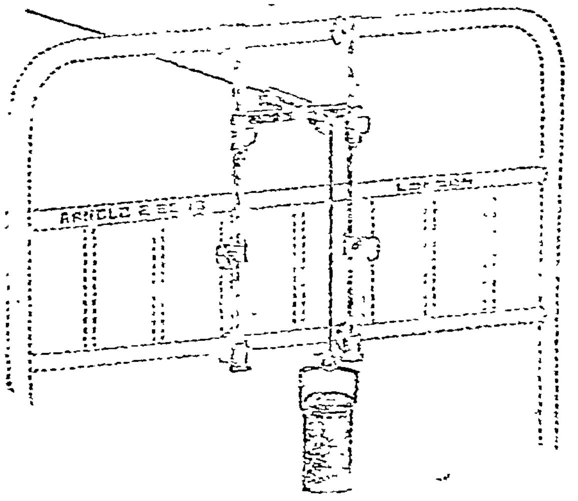


Opinions differ very much concerning the treatment of gonorrhœa by the use of antiseptic and astringent injections, but the majority of those who see much of the disease order injections of some kind to be used during one stage or another. There can be no doubt that if an injection is to do any good at all it must be properly administered, and much of the failure of injections to hasten the cure must be attributed to the inadequate method of use. Messrs. Down Brothers of 21, St. Thomas's-street, London, S.E., have made for me a back-flow catheter through which any quantity of fluid can be made to irrigate the whole urethra without entering the bladder. The instrument is composed of a metal catheter, with a bulbous extremity, curved in the ordinary way. The eyes of the catheter consist of three apertures situated at the junction of the stem and the bulb. The greatest diameter of the bulb is three sizes larger than that of the stem. I have found that No. 4 for the stem and No. 7 for the bulb is the most useful size. The shoulder of the bulb fills up the urethra in front of the eyes and all the lotion escapes in a rapid stream at the side of the stem. The best arrangement is to attach the instrument by means of a rubber tube to a can containing one quart of the lotion. The instrument is passed with the ordinary precautions as far as the compressor urethræ, when it is natually arrested. This is far enough for a case of anterior urethritis, but in posterior urethritis the instrument should be passed into the bladder, and then withdrawn until the bulb is felt to be just grasped by the vesical orifice. The douche can is raised three feet above the patient's bladder and the quart of lotion takes from three to five minutes to run out. An intelligent patient can be taught to do this for himself night and morning, and provided he sterilises the catheter each time there is no more risk of septic infection than when he uses an injection with an ordinary glass syringe. The rapid improvement in cases where it is used will soon convince anyone of the practical utility of the device. An ordinary glass syringe can, of course, be used instead of the douche can.

Ernest W. Hey Groves, M.D. Lond., F.R.C.S. Eng.,
Assistant Surgeon to the Bristol General Hospital.

THE NORLEDGE EXTENSION APPARATUS.

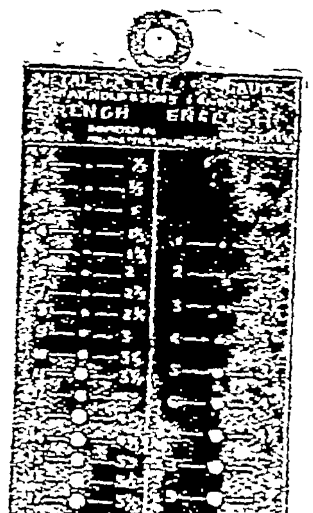
The illustration represents an extension apparatus for surgical purposes which seems to me to possess advantages over those at present in use. Some of its special features are that it is free from vibration, simple in construction, easily fixed, portable, sightly, and can be rendered aseptic. The apparatus consists of a frame having adjustable hooks by which it can be hooked on to the rails at the foot of the bedstead and to the frame is adjustably attached a tube through which runs a cord, having at one end means of attaching it to the leg of the patient and at the other end a weight or shot-can, a pulley being provided for the cord to pass over. A convenient form of the apparatus is two bars, each having a rigid hook at the upper end and an adjustable one at the lower end. On these bars slides a cross bar, detachable in any required position and carrying a tube having a pulley at one end, through which tube passes the cord. The makers are Messrs. Arnold and Sons, West Smithfield, London, E.C.



Charles D. Muspratt, M.D. Lond., F.R.C.S. Eng.,
Surgeon to the Royal Victoria Hospital, Bournemouth.

A NEW METAL CATHETER GAUGE.

I have usually found that a considerable amount of vagueness exists, not only about the numbers and diameters of the French and English catheters respectively, but also on the relation the two scales of measurement bear to each other. To obviate this I have devised the following instrument, of which the accompanying figure is an illustration. By an omission the last three numbers of the diameter in millimetres of the French catheters have been left out in the figure. The gauge is made of German silver (polished) and is 12¼ inches in length and 5 inches wide. On the left-hand side the number and diameter in millimetres of the French catheters are represented, and on the right side the English. By using this gauge not only can the number and diameter in millimetres of any metal catheter be determined at once (and this is a great advantage where the numbers are only placed on the stylets, which are liable to be put back into the wrong catheters) but also the relation the French scale bears to the English can be appreciated at a glance. The gauge can be sterilised by boiling and does not tarnish. It has been made at my suggestion by Messrs. Arnold and Sons, West Smithfield, London, E.C., who after several trials have successfully surmounted all the technical difficulties in connexion with its manufacture.



Cecil H. Leaf, M.B. Cantab., F.R.C.S. Eng.,
Surgeon to the Cancer Hospital and to the Gordon Hospital for Rectal Diseases.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 8, 1906.

The Meaning of Scientific Method.

IF the average citizen were asked to describe the method pursued in scientific investigation, he would probably answer somewhat to the effect that it consisted in the observation of phenomena and the record of what was observed—that the chemist mixes various substances in his test-tubes or heats them in his crucibles and retorts and observes what takes place; that the biologist collects his plants or animals and arranges them according to their resemblances in groups; that the astronomer studies the movements of the stars and notes their positions and relations on a map. The average citizen might add that the use of instruments of precision is necessary to such observation, but he would still probably regard mere record of particulars as the essence of science. In such an answer there would undoubtedly reside a large portion of truth, since accurate observation is the first requisite of every branch of knowledge and the majority of researchers must be content with such work alone, leaving to a chosen few the processes of inference and generalisation; but it would be a small portion only of the whole truth. Yet it may be doubted whether many among the large army of workers in the field of science would be prepared to supply off-hand an adequate account of the methods pursued in scientific advance. We reason intuitively and leave it to the logicians to analyse the processes of thought. Hence actual advances in knowledge have always preceded the formulation of new methods of scientific investigation. In days long ago the mathematical sciences were carried to a high-pitch of perfection, and with this came ARISTOTLE'S masterly analysis of the deductive method of reasoning, to which little or nothing has been added in more recent times. The revival of the study of nature, which in the sixteenth century followed the overthrow of blind belief in traditional wisdom, was the forerunner of BACON'S "Novum Organum," or new instrument of scientific inquiry as analysed by him. This was the inductive method, which had been known indeed to ARISTOTLE but not invested by him with that importance which it was afterwards to attain. Yet, in truth, neither the inductive method by which we infer universal laws from a series of particular instances, not the deductive method by which we descend from general rules to individual phenomena, is alone sufficient for our purpose when we investigate the secrets of nature. Both intellectual instruments must be used in combination, as was seen by MILL, whose work coincided with the rapid growth of scientific knowledge at the beginning of the nineteenth century, a growth which has continued uninterrupted to the present day. Very interesting examples of the mode in which great scientific discoveries have been made are given in a collection of lectures[1] recently delivered at Oxford, which are now published by the Clarendon Press. One of the most notable instances is that of NEWTON'S discovery of the law of gravitation as set forth in his "Principia." The laws of motion as we know them were first discovered by inductive reasoning, and from them NEWTON deduced mathematically—that is to say, deductively—the truth that every body which moves in an elliptical orbit around another body lying in one of the foci of that ellipse is drawn towards the latter by a constant force. The planets are therefore drawn towards the sun by such a force. Starting from this result of deductive reasoning NEWTON advanced by a further induction to the universal law that all bodies are mutually attracted, in other words to the general law of gravitation. Both methods of logic were therefore necessary for this grand scientific generalisation.

The methods of reasoning adopted in the field of science do not differ in essence from those employed in forming judgments in the affairs of ordinary life; but the degree of accuracy demanded is higher, and for the purpose of attaining thereto constant verification of the conclusions arrived at is practised. The attitude of the scientific observer is one of scepticism on all points which seem to depend merely upon the dicta of authority. Accepted conclusions are constantly being discarded in the light of further knowledge, and closer and closer approximation to the truth thus constantly obtained. Only a short time ago nothing seemed more certainly established than the immutability of the chemical elements; now the old Heraclitean doctrine of continual change seems to be in process of revival and the mutability of the elements themselves is freely canvassed, if not yet generally accepted. If this constant change of doctrine is true of the physical sciences such as chemistry and astronomy, how much more may we expect to find it in the more complicated and therefore backward branches of knowledge dealing with life and with mankind? Here opinions must undergo a ceaseless, if often imperceptible, evolution. The once firmly established doctrines of Individualism and of Free Trade are now being subjected to a scrutiny as to their claims to constitute true generalisations, and the result of the examination is as yet obscure. Unfortunately, in the sphere of politics scientific methods are discarded; a system in which conclusions are reached by counting heads of partisans on either side is not conducive to a rapid process of ascertainment of truth. Yet even to political questions the logical methods to which we have previously alluded are ultimately applied, and the advance of knowledge is only checked, not arrested, by the idols of the market-place to which any particular generation bows the knee. That even temporary obscuration of truth is possible in these matters is due to the complexity of the problems presented by social inquiries, from which it results that accuracy such as is attainable in the more abstract sciences is here impossible.

But this complexity is not confined to social questions, it is present to an almost overwhelming degree even in the comparatively simple problems of physiology; it is still more perplexing in connexion with the realm of nervous and mental activity. In the science of pathology, and consequently in the associated art of medicine, the difficulties of research are manifest. Experiment is practically impossible on the human subject and verification of theories is thus as a rule prevented. Nor are extraneous obstacles arising from accepted doctrines and popular prejudices by any means absent. But the physician must endeavour rigorously to apply the methods of scientific research in these as in other fields. He must resolutely decline to submit his judgment to the fetters of ancient authority, however firmly they may seem to be riveted. He must submit his conclusions constantly to the touchstone of facts. He must realise that reason will be the guide to his steps, and that the passions of controversy and the prejudices of popular ignorance are alike hostile to true progress. Innovators are usually disliked and run the risk of being regarded as heretics and socially, if not ecclesiastically, excommunicated. Some of these independent spirits, however, in the end win niches in the Temple of Fame, when the discredit of having placed obstacles in their path becomes very terrible. Formerly it was expected that the public would be ready to view all new medical discovery with suspicion, but the present condition in the world of medical science does not quite agree with this picture. The public seems to us to be almost gullibly anxious for new theories in diagnosis and new processes in therapeutics, and a grave responsibility is thereby put upon the medical man. He has to make up his mind, often upon insufficient data, whether certain developments are proceeding along the line of proven knowledge and constitute progress, or whether they are vagaries to be disregarded and condemned. If he acquiesces in the new suggestions he knows that the public will readily follow his suit, if he puts his veto upon a trial of them he, the man of science, may be a stumbling-block in the path of science. How true is the saying, Once a student of medicine always a student. Only the resolute intent to keep abreast with developments in our knowledge can assist the practitioner in such difficulties.

The Feeding of School Children.[1]

WE have already had opportunity of commenting on the proposed measure for enabling local authorities to provide meals for those children in public elementary schools who are in need of such assistance, and have pointed out the difficulties which the problem presents when practical means have to be devised for carrying out this necessary duty. On the one hand, it is clearly indefensible to insist upon any child undergoing school discipline when owing to insufficient food it is not in a fit state to benefit by the instruction given. On the other hand, any attempt to institute a system of free meals for indigent children brings us face to face with the problem of selecting those who are proper recipients of such charity, for we must prevent any possibility that merely lazy or careless parents should take advantage of the provision to enable themselves to shirk a still further portion of their duties towards their children. The report of the Select Committee to whom the Bill introduced into the House of Commons was referred is now issued, and we have further means of judging of the form the measure is likely to take. The report shows clearly that the committee was deeply impressed with the difficulties to which we have alluded and is anxious to find means of steering safely between Scylla and Charybdis. It points out in its preliminary remarks that evidence goes to show that the number of children who are in actual need of food is relatively very small, one witness stating that in West Ham, a very poor district, the number of children fed at present by a charitable agency was only about 1000 out of a total of over 53,000 attending the schools. Nor is the need a constant factor, being much less urgent in the summer than in the winter months. At present there do not exist any satisfactory means of ascertaining the real number of children who are in need of sustenance, since the teachers are not trained so as to be able to distinguish starvation from other causes of wasting—and indeed it is not by any means a simple problem even for a medical man in all cases. We are glad to see that the committee realises the importance of that medical inspection of children at our elementary schools upon which we have always insisted. Thus it reports: "The committee attach importance to the power proposed to be given in Clause 35 of the Education Bill now before Parliament to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition of the children." Whatever view medical men as citizens may take as to many of the provisions of this last-mentioned Bill, there can be no hesitation among them, as members of the medical profession, in endorsing this proposal as useful and indeed indispensable.

Turning to the economical recommendations of the committee, we find that it holds that the educational authority and not the boards of guardians should have the responsibility of administering the measure. The cost of the meals should be recovered from the parents of the children, but if they are unable or unwilling to defray it the guardians are to be called upon by the school authority to find the money and are to undertake the recovery of it from the parents. All inquiries into the condition of the children are to be made by the educational authority, the Poor-law officers affording them any aid required, but precautions are to be taken to avoid any stigma of pauperism attaching to particular children. It is not, however, contemplated that in the majority of instances the money for the actual provision of food should be supplied by public funds; it is hoped that it would generally be forthcoming from charitable sources. The school authorities are merely to furnish the necessary buildings and to supervise the distribution of the meals. In the case of any very poor districts, in which voluntary agencies may fail to supply the food, public money may be made available, but not to an amount exceeding that produced by a ½*d.* rate throughout the district. As we have previously pointed out, we have little confidence in this limitation; should the amount thus provided be insufficient the outcry for more will be irresistible when the principle of providing meals has once been adopted. There is also a real danger that charitable contributions will dry up when it is realised that the subscribing donors are merely saving the rates and taking upon themselves what they may well regard as a duty to be shared by all alike. In the case of parents wilfully refusing to feed their children or to pay for the meals provided it is clear that legal compulsion must be employed, and the question arises as to the authority which is to undertake the task of prosecution. The committee recommends that this duty should be discharged either by the guardians or by the Society for the Prevention of Cruelty to Children. With regard to the latter, we cannot refrain from questioning the advisability of intrusting public work to a private body enjoying no recognised State sanction. The society does much admirable work, but it should not be called upon to undertake duties which the State by legislation has laid upon itself.

---

[1] Special Report and Report from the Select Committee on the Education (Provision of Meals) Bill, 1906, and the Education (Provision of Meals) (Scotland) Bill, 1906, with the Proceedings of the Committee. (Wyman and Sons, Ltd., Fetter Lane, E.C.)

Apart from this feature we have little criticism to offer upon the suggestions of the committee. In breaking such new ground as is here done, first steps must be hesitating and tentative. The local educational authority is to delegate its powers to a committee comprising representatives of the voluntary subscribers as well as of itself, along with delegates from the board of guardians and from the local branch of the Society for the Prevention of Cruelty to Children, if the two last elements seem desirable. Stress is laid upon the importance of encouraging the association of voluntary helpers with the school authorities. The meals are not to be given in the actual schoolrooms if this can be avoided, owing to the difficulty which would thus be created of properly cleansing and ventilating the rooms. This is certainly a wise provision. So, too, is the stipulation that it should not be made a condition of appointment for any teacher that he or she shall, or shall not, take part in dispensing the meals provided for the children. We cannot but think that the action of the London Education Committee in exacting this service from their teachers is indefensible. The health of the teacher should be no less an object of consideration than that of the children, and such additional work as is implied in supervising the distribution of meals tends to curtail unduly the midday period of rest which forms a necessary prelude to the afternoon labours. Teaching a large class is in itself an exacting duty, quite sufficient for the strength of most of those who are engaged in this occupation. It is unjustifiable to add to the stress by a demand that the teachers shall "serve tables." Precedent suggests that special helpers should be provided for this duty, or the more technical work for which the teachers are appointed will inevitably suffer.

Death Certification at Bootle and Elsewhere.

THE infantile and uncertified mortality in the borough of Bootle, which was formed in 1868 out of a northern suburb of Liverpool, and includes a large portion of the Liverpool docks, has lately been made the subject of a controversy between the medical officer of health, Mr. T. W. NAYLOR BARLOW, and the county coroner, Mr. SAMUEL BRIGHOUSE. The latter gentleman, a layman, has defended himself with somewhat unnecessary energy against what he conceived to be imputations cast upon him by the former, but which were, in reality, no more than suggestions for the better protection of the public by a modification of the procedure now adopted for inquiring into the probable causes of uncertified deaths. Mr. BARLOW will, we think, be fully sustained by public and professional opinion in the position which he has assumed, and it may be hoped that Mr. BRIGHOUSE, on farther reflection, will realise that he has stood upon the defensive somewhat prematurely, and before he had been made the subject of attack. In Mr. BARLOW's annual report for 1905, which was issued in June last, he called attention to the contrast between the steadily improving and very satisfactory general death-rate of the borough and the high infantile death-rate, the former having been 17·3 per 1000 and the latter 153, including 83 deaths from diarrhœa. He expressed his conviction that the period of 42 days, which may now elapse between the birth and the registration of an infant, is far too long, as it permits many children to escape registration altogether. The parents leave the district before the six weeks have expired and migrate to another in which no inquiry is made about them. The interval also gives ample time for the death of an infant from neglect or improper feeding before any intimation of its having been born has reached the lady sanitary inspector of the district, whose first visit of inquiry may be met by the reply that the child is dead and buried, and often by abundant evidence that it has died from some cause which her advice and instruction might have obviated. Mr. BARLOW's mortality tables show that in Bootle about 30 per cent. of all deaths of children under one year occur during the first six weeks, and he thinks it probable that many of these lives would be saved to the State if births were registered immediately.

So far, of course, there is nothing which could afford the coroner any reasonable ground of complaint, but a subsequent passage of the report sets forth that in 38 cases within the borough the cause of death had not been certified by a medical man and that no inquest was held upon any one of them. Mr. BARLOW goes on to say that it is within the discretion of the coroner to hold an inquest in any case of uncertified death, and states his belief that that official decides the question on information forwarded to him by the police. He then points out that the ordinary policeman is quite unsuited to make inquiries for the information of the coroner, and that the existing practice really leaves the cause of death to be determined and declared by the relatives of the deceased. He expresses a strong opinion that an inquest should be held in every case in which the death is uncertified, unless the coroner can satisfy himself as to the facts, not by the report of a policeman or coroner's officer, but by that of a medical man who knew the deceased and who may have attended him recently. He thinks it especially necessary that an inquest should be held when the uncertified death is that of a young child, and he refers to the facility, no doubt only too familiar to him from official experience, with which undesired or illegitimate children may be got rid of. On June 20th, soon after the issue of the report and actually in the course of an inquest arising out of an explosion at Havorford, the coroner addressed the jury and the press on the subject of Mr. BARLOW's observations, and described them as "instructive, amusing, and inaccurate." The "amusing part," he said, "was that which ascribed to the lady sanitary inspector and the medical officer an ability to determine that all infants whom they had not seen either alive or dead would have lived if the mothers had received the lady's instructions as to feeding and care." We will not dispute with the coroner as to whether or not this "part" is "amusing," but will be content to point out that we have not been able to find it in the report. The coroner went on to say that if he "held inquests so as unnecessarily to obtrude into private sorrow, the whole of South Lancashire would be inflamed against him," and we trust that we shall not be thought wanting in respect either to the gentleman himself or to his office if we express a hope that the press report may be inaccurate and that he did not really say anything so foolish. Mr. BRIGHOUSE, however, went on to say that there had been "48 cases of uncertificated death instead of 38," and that every case had been "carefully investigated by the police," which was precisely the charge brought by Mr. BARLOW against the customary procedure. The coroner added that the police "often inclosed medical reports," that he had held an inquest in every uncertified case of the death of an illegitimate child which had been reported to him, and that the "reflections" cast upon him by Mr. BARLOW were "uncalled for," and not substantiated by any statistics or facts. The jury, at the close of the coroner's address, adopted a vote of confidence in him, and he, in expressing his thanks, "was glad to find they did not think him to be as black as painted by Mr. BARLOW." The health committee of the borough immediately took steps to support its officer, and three days later, on June 23rd, it passed a resolution fully approving of the observations in Mr. BARLOW'S report, "which contained no reflection on the district coroner," and expressing the opinion that the present mode of registering uncertified deaths is "highly unsatisfactory." On August 1st this resolution was accepted and confirmed by the borough council as a whole.

In the borough of Bootle, as in many other places, there may possibly be wheels within wheels the working of which is not immediately manifest to distant observers; but apart from this consideration it seems plain that the somewhat too sensitive *amour propre* of the coroner has led him to attach a sense of personal animadversion to words which should be interpreted only as a criticism of official customs. Our Registration Act has been in operation for nearly 70 years, and no one, unless it be Mr. BRIGHOUSE, now disputes that its provisions are insufficient for the proper protection of life, and especially of infantile life. Its deficiencies can be, and are in great part supplied by coroners, and we have no doubt that the general feeling among them is one of willingness to hold an inquest in every case of infantile death, in which there is even a suspicion that life may have been sacrificed by the negligence or the self-indulgence of parents. Except in cases of manifest violence the police are not qualified to make preliminary inquiries for the purpose of discovering the cause of death. They do not possess the knowledge necessary for sifting the statements made to them, and cannot form any sound conclusions concerning their probability or their value. The police are, as a rule, an excellent and a worthy body of men, but they are drawn from classes in which the traditional value of infant life is not high. It was, we believe, a jury of Devonshire farmers, empanelled to inquire into the cause of death of an infant discovered in a ditch, who returned the verdict "we find as it bain't no odds to nobody," but the sentiment of which this verdict was an expression is very widely diffused among the working classes, and not least among the rural peasantry, from whom our policemen are largely recruited. We wish that statistics were obtainable by which the infantile mortality of districts in which coroners are lax could be compared with the same mortality in districts in which they might be described as severe, for we have little doubt that a very marked difference would be displayed between them.

Annotations.

"Ne quid nimis."

POPULAR ERRORS REGARDING MUSHROOMS.

THE distinctions between edible and poisonous mushrooms are usually based on empirical grounds, with the result that mistakes of a serious nature may, and often do, occur. The subject has recently received the attention of Professor Labesse, who has described in *l'Anjou Médical* the characters whereby edible and poisonous mushrooms are distinguished in various localities. Many popular tests for determining the wholesomeness or otherwise of a mushroom are based on colour, odour, taste, and texture; on the presence of rose-coloured lamellæ or a milky juice; on the situation in which the fungi grow; and on the action of the mushrooms on various substances, including gold and silver coins, milk, and onions. Thus, according to one popular notion, mushrooms having a blue, violet, green, or red colour are unfit for food, but this test would exclude many wholesome fungi, including the green *Russula* and the green *Clitocybe*. It has been said that only mushrooms which do not change colour when cut are good to eat, but *Lactarius deliciosus*, some species of *Boletus*, and many other mushrooms which change colour are perfectly harmless, while, on the other hand, *Amanita muscaria* and some other fungi which do not change colour when cut should be avoided. Professor Labesse points out that the presence of an agreeable odour is not an infallible test of a good mushroom, as a species of *Amanita* (*l'Amanite phalloide*) is especially dangerous in spite of its pleasant odour. There is a dictum among certain amateur gatherers that a good mushroom has a grateful taste. This test is useful in many cases but not in all—e.g., *l'Amanite phalloide* and *la Fausse Orange* (*Amanita muscaria*) are scarcely bitter but quite unfit for eating. As regards texture it is generally regarded that compact, brittle mushrooms, with a dry skin, are edible, but Professor Labesse considers this to be a mere prejudice, as the eating of certain species of *Russula* would seriously indispose anyone placing confidence in these characters. Mushrooms with rose-coloured lamellæ are usually considered to be edible but this is a false notion, some species of *Volvaria* and other poisonous fungi possessing this character. Mushrooms with a milky juice are regarded as dangerous by some collectors but this rule must not be followed too literally as many excellent members of the genus *Lactarius* would thereby be excluded. The situation in which mushrooms grow is a very uncertain criterion of edibility. Thus, it would be dangerous to regard all mushrooms growing in meadows, open fields, and roadsides as good, since many suspected kinds grow in such places.

On the other hand, mushrooms growing in coniferous woods and under trees generally have been condemned, but the succulent *Lactarius deliciosus* grows in coniferous woods and the edible *Pholiota* grows under poplars, while species of *Helvella* and *Hydrum*, which flourish in shady woods form a wholesome dish. The blackening of a gold or silver coin or ring does not prove a mushroom to be poisonous; the blackening is generally due to more or less decay in the mushroom, as fresh mushrooms, whether poisonous or not, fail to blacken these metals. The curdling of milk by mushrooms is another property which has nothing in common with toxicity, the cause of the curdling being attributable to the presence of an acid or a ferment. An old custom consisted in dipping a white onion or a clove of garlic into the cooking vessel containing the mushrooms and noting whether the latter turned brown or not; the presumption that only noxious mushrooms are turned brown by this treatment is not justifiable, since some non-poisonous varieties do change colour in this way while some poisonous varieties do not. It is a common belief that slugs and insects attack edible mushrooms, but this is by no means universally true, as the deadly *Amanitas* are attacked by slugs, while many wholesome fungi are respected by these depredators. The tests so far described are largely of a rule-of-thumb nature, but another test which has received wide acceptance depends upon the fact that many poisonous fungi are surrounded by a *velum universale*, notable examples being the intensely poisonous subgenera *Volvaria* and *Amanita* and the puffballs. But, like all other rules, this is open to exceptions, including the genus *Agaricus*, to which the common mushroom, *A. campestris*, belongs. Professor Labesse considers that there are no practical empirical means by which amateurs may with confidence decide whether an unknown fungus is good to eat. There is often a risk taken in eating mushrooms, and those who do not wish to incur the risk are reminded by Professor Labesse of the method adopted by Gérard in 1850. He boiled the mushrooms for some time in salt water, threw away the water, and exposed the mushrooms to the air. He fed his family for nearly a month upon all kinds of poisonous mushrooms treated in this way and found them to be nutritious, though less palatable than mushrooms cooked in the ordinary way. Professor Labesse suggests that not more than one mushroom in ten is poisonous and that the best test consists in rejecting those which have a ring at the base of the stipe. Deadly mushrooms as a rule possess a ring or annulus consisting of the remains of the *velum partiale* which covers the young mushroom and is fractured during growth. In order to apply this test the mushrooms must be gathered with care. Unfortunately, in rejecting mushrooms possessing this character some excellent varieties are rejected in addition to the commonest poisonous varieties. Amateurs should know the characters of the mushrooms which grow in their neighbourhood, restrict themselves to certain kinds which they know to be edible, and in cases of doubt should abstain altogether.

THE PSYCHOLOGY OF THE SELFISH MOTORIST.

THE advent of the motor-car has afforded us an illustration of two human traits: one the long-suffering of some non-motorists, the other the blindness of some motorists to the claims of others to the use of the road. This latter trait has developed to such a degree that the medical question may arise whether we may not have here some pathological phenomena associated with the possession of a motor-car; whether, in fact, the driving of such a vehicle may not lead occasionally to such a condition of auto-concentration as to leave the driver for the moment utterly unmindful of all other interests than his own. Be this as it may, this callousness to the rights of others only became apparent with the introduction of motor-cars, and the disease, if so it may be termed, has undergone a marked exacerbation during the recent spell of rainless weather. Behind many motor-cars is a trail of blinding dust noticeable in some circumstances for fully half a mile, producing a temporary eye and throat soreness among those whom it envelops and rendering the air for the time being quite irrespirable. Of all this too often the selfish motorist appears to be entirely unconscious; he passes on his way regardless of all the discomfort which he occasions, unmindful of what he leaves behind, and concentrated alone on what is to be seen ahead. Without the least compunction he rushes through the villages, raising excrement-bearing dust into the atmosphere to be carried indiscriminately into the eyes and throats of the villagers and on to the meat, milk, and other articles exposed for sale as human food. Much of all this obvious injustice might be avoided were all motorists (as some are) possessed of elementary good taste or fellow feeling, and were ready to slacken speed in circumstances wherein the dust which is raised is likely seriously to inconvenience other users of the public thoroughfares. The pathological side of the selfish motorist is still further accentuated by the fact that for the most part he is creating a nuisance for his own private purposes. There is no reason, other than self-indulgence, why the selfish motorist should pass from one place to another under conditions which materially detract from the comfort of other people, raising fæcally laden dust and increasing the chances of dust-borne infections or augmenting the cough of the unfortunate consumptive living by the wayside. It must be recognised that there are motorists who are mindful of the comfort and claims of those who use the high roads for purposes other than those of pleasure, but their virtues are obscured by the failings of the unscrupulous scorcher, and they suffer with him in the general esteem.

THE PREVENTION OF CRUELTY TO CHILDREN ARISING OUT OF NEGLECT TO SEEK MEDICAL AID.

WE are all familiar with the cases in which parents or other responsible adults are indicted for manslaughter when a child has died, and it has been made plain at an inquest that life would have been saved by timely medical aid. Similarly actions for neglect arise when the child has been caused unnecessary bodily pain by the failure to provide medical assistance. Examples of this kind of legal proceeding have been afforded by the members of the sect called the "Peculiar People," who regard the summoning of medical aid as contrary to the teaching of the Bible, and sometimes by cruel and negligent parents obviously indifferent to the welfare of their offspring. "Christian Scientists" are apparently too well conversant with the danger of prosecution to carry their principles in the case of their children to the bitter end, and, so far as we are aware, no such prosecution as that recorded in another column (see page 696) has been instituted against one of them. We think it highly desirable that the full extent of the legal responsibility of parents in the class of cases indicated should be tested to the utmost before judges, but it is only possible thus to elucidate the law when ample pecuniary means for doing so are possessed by both parties. The case in question, it will be seen, is one in which, through no desire to be unkind to a child (who is still alive) and probably with a sincere desire to save him from suffering pain, a mother refused to submit him to a surgeon, and the National Society for the Prevention of Cruelty to Children acted as prosecutor in compelling her to comply with medical advice. We should like to see settled the extent of a parent's criminality under the statutes relating to cruelty to children in circumstances of this kind, and we print a full account of the proceedings for this reason. It will be plain to medical readers that Mr. E. MacDonald Judge gave his evidence fully and clearly, and gave none that he was not entitled to give. It will be seen also from the report that it was made quite plain by him that no surgical interference with the child would have been undertaken upon his opinion only, or without full examination and consideration by what the magistrate termed a "specialist"—i.e., by the surgeon upon whom the responsible duty of operating might fall. Mr. Baggallay said that "the society should have had a specialist," but how this was to be done he did not suggest. The mother had apparently at some time allowed Mr. Judge to examine her child, but she had refused to take him to the hospital. By what means could the mother have been compelled to submit her child to the examination of the specialist? In the absence of such examination a consulting surgeon, it is true, might have corroborated or contradicted Mr. Judge's deductions from the facts which he described, but there is nothing in Mr. Baggallay's observations to show that an opinion thus formed and expressed would have been regarded by him as satisfactory. But the high value set by Mr. Baggallay upon the specialist's knowledge is a little inconsistent with the order to the little boy to exhibit his powers of walking in the court, apparently in order that a layman might estimate the extent of the disease and the treatment required. We quite understand that on the face of it the necessity of a further operation seemed remote when the child was seen to cross the court without crutches, but only a surgeon can say how far such a feat has any real significance. Certainly the inferences could hardly be drawn from it that there was absence of medical evidence proving the necessity of operation, or that there was undue haste on the part of the National Society for the Prevention of Cruelty to Children. The mother had declared her intentions in plain terms not to have a further operation performed, but delay might be very undesirable in the interest of the patient. If we here mention the patient in the second place only, we do so in order to accentuate our view that throughout the hearing the feelings of the mother seem to have been the matter primarily considered, and that the good of the patient was treated as a matter of secondary importance. The prosecution might with advantage have produced the evidence of the surgeon at the hospital, or hospitals, where the previous operations had been performed, but it must be remembered that to bring such witnesses needlessly to a police court is undesirable and expensive; and prosecutions of this kind are not undertaken by the police or by the Treasury, but by a benevolent society whose means are not unlimited and whose methods and expenditure are rightly subjected to careful scrutiny. Mr. Baggallay is known to everyone as a humane and learned magistrate, but whatever the rights and wrongs of this particular case may be, questions have been opened up by it that have not been settled by the magisterial decision.

A CASE OF ANTHRAX AT EXETER.

A RECENT inquest held at Exeter disclosed a case of death from anthrax where probably a fatal result might have been averted had the infected person sought medical aid with promptitude, while the difficulty of tracing the source of the poison was strikingly exemplified. The deceased, a man named Burden, employed at a tanyard, observed pimples upon his left arm on August 11th, which had begun to be badly swollen on the following Wednesday. On the next day, Thursday, he first consulted a medical man, and on the following day, Friday, he was admitted to the Royal Devon and Exeter Hospital, where he died two days later, microscopic examination confirming the opinion formed at the hospital that he was suffering from anthrax. Evidence was given as to the care taken by the employers with regard to hides, as to the provision of gloves for the men, and the posting of notices to meet cases of the kind described. A member of the firm said that he would have driven the deceased to the hospital at once had he known of the symptoms when they first appeared. With regard to the origin of the anthrax, the firm dealt in English market hides, and for two or three years had not bought foreign hides, with the exception of 50 Oporto hides purchased three weeks before the man's death. These, however, according to the evidence, he had not handled, nor, in fact, had they been dealt with at all. The deceased had handled many hides during the days preceding the development of the symptoms referred to, but had only skinned one animal, to which attention was thus directed. It was a cow, the property of a farmer who was named, and it had died suddenly, but a veterinary surgeon had stated that it had been struck by lightning, and the deceased had observed a mark on its skin which, in his opinion, confirmed this view. It does not appear from the report before us that either the farmer or the veterinary surgeon was called to give evidence, but it is not easy to believe that they and the man who skinned the cow should all have been mistaken, and the case remains mysterious, as the jury found by their verdict, which ran: that the deceased accidentally contracted anthrax but that there is no evidence to prove how he did so.

THE TREATMENT OF ACUTE EMPYEMA BY SIMPLE INCISION.

THE current teaching is that empyema should be treated by resection of the ribs and drainage. In the *American Journal of the Medical Sciences* for July Dr. J. F. Leys advocates the treatment of acute empyema by simple incision—a simplification which he thinks ought to commend itself to general practitioners who do little surgery and are loath to undertake such an operation as resection of ribs. In the case of chronic empyema he admits that adequate drainage may not be secured without resection of one or more ribs. Such removal of bone is required when expansion of the lung does not proceed and is not an effective aid to the expulsion of pus. Special forms of drainage tubes he also thinks unnecessary. The treatment of empyema by simple thoracotomy is not new and has been successfully practised since the time of Hippocrates but has fallen out of fashion. In 1899 Dr. E. Andrews of Chicago deplored the fact that surgeons advocated resection of ribs in all cases of empyema. Professor W. Osler writes: "It is sad to think of the number of lives that are sacrificed annually by the failure to recognise that empyema should be treated as an ordinary abscess by free incision. The operation is by no means serious." Dr. Leys relates five cases of acute empyema successfully treated in the United States Naval Hospital by simple incision. They all occurred in boys between the ages of 16 and 17 years and in four the empyema was a sequel of pneumonia. The treatment was such as any practitioner could carry out. Local anæsthesia was produced with a lump of ice dipped in salt and held against the chest, with the ether spray, or with ethyl chloride. The instruments used were a scalpel for incision, a pair of blunt straight scissors for enlarging the incision, two pairs of hæmostatic forceps to hold open the incision for the flow of pus, to introduce the drainage tube, and to catch bleeding vessels if encountered, about 12 inches of three-eighth inch rubber tube fenestrated at intervals of an inch, and four large safety pins. All these instruments and the dressings were sterilised. The following is one of the cases. A lad, aged 17 years, was admitted on March 4th, 1901, with pneumonia of the left lower lobe. On the 17th there were signs of right pleural effusion. The temperature declined irregularly and was normal from the 18th to the 20th, when exploration showed that the effusion was serous. The effusion increased rapidly and the fever returned. On the 24th the effusion reached to the clavicle and 1925 cubic centimetres of creamy pus were removed by aspiration. On the 25th under local anæsthesia a free incision was made in the sixth interspace near the posterior axillary line. Two fenestrated tubes six inches long were inserted and about 1500 cubic centimetres of pus were removed. The temperature fell to normal. Good drainage was maintained and the wound was dressed daily. On the 31st pulmonary gymnastics were begun. By April 15th the daily discharge amounted to only two ounces. The tubes were gradually shortened and one was removed on the 19th. The pus contained an abundance of pneumococci and other cocci. The discharge continued until May 12th and on the 14th the second tube was removed. The fistula had completely healed on the 24th. Complete recovery was attained.

AN INTERNATIONAL CONGRESS ON THE CARE OF THE INSANE.

An international congress on the care of the insane (*Congrès International pour l'Assistance des Aliénés*) will be held in Milan from Sept 26th to 30th. The two principal subjects of discussion will be: (1) Improvements in the Care of the Insane and especially in their Home Care (*assistance familiale*) in various countries from 1902 to the present day; and (2) the Creation of Departments of Observation, Supervision, and Isolation in Asylums and Colonies, together with an account of the methods which have given the best results. Besides these there will be six subjects of discussion relative to the care of recently recovered lunatics; the care of special classes of insanity, such as delusional, epileptic, alcoholic, and moral insanity, with special reference to home care; psychiatric and neuropathological dispensaries; sanatoriums for nervous diseases; the economic and social results of the care of the insane; and the relation of the State to the care of the insane. Dr. L. Frank, superintendent of the asylum at Münsterlingen, Thurgau, Switzerland, will in the course of the meeting describe his scheme of an international bureau for the scientific study of the causes of insanity and the best means of prevention. The official languages of the Congress will be Italian, German, English, and French, the latter being recommended for preference. Members of the Congress pay a contribution of 20 francs and ladies accompanying them pay 10 francs. The treasurer, to whom remittances may be sent, is Dr. Edgardo Morpurgo, 5, Via Bigli, Milan.

THE USE OF ALCOHOLIC FLUIDS.

We have received from the secretary of the Newcastle-upon-Tyne United Temperance Electoral Council, Mr. Robert P. Moncrieff, the president of which is Dr. F. C. Coley, a copy of a circular which, we are informed, has been sent to every member of the medical profession in Newcastle, Gateshead, and Gosforth. The circular opens with a letter from Mr. Moncrieff stating that he declines to become an annual subscriber to the Royal Victoria Infirmary because sundry members of the liquor trade have consented to supply wines and spirits to the infirmary for 1906. The circular goes on to state that there is a great deal of falsified wine, that spirits are adulterated with a variety of matters, and concludes with a quotation, attributed to the late Sir B. W. Richardson, in which that physician says that when he wanted to administer alcohol he wrote it on the prescription as absolute alcohol. The circular ends with a query initialled by Mr. Moncrieff which runs as follows: "How can medical practitioners fulfil the conditions laid down by Dr. Richardson, when they employ brewers, publicans, and wine merchants as their dispensers?" We think that this circular is an unwise production. We are fully aware of the evils wrought by the over-consumption of alcoholic drinks. We are also fully aware that some brewers and distillers and wine merchants sell beer, spirit, and wine which are not everything that they should be, but the circular implies that the purveyors of liquor whose names are given will deliberately supply the Newcastle Infirmary with falsified stuff. It allows that vinous ethers do good in certain cases of illness but it asks, "If ethers are required why not administer them in a pure medicine?" Mr. Moncrieff ought to know, as he has taken up so vigorous and combative an attitude, that genuine brandy, rum, champagne, and burgundy, all of which there is not the slightest difficulty in getting provided application is made to a reputable house and the proper price is paid, do contain ethers "in a pure medicine." The controversy which is now going on concerning the use of alcohol entirely ignores the fact that all alcoholic liquors, apart from pharmacopœial tinctures, when administered in a hospital should be so administered on account of the secondary products which they contain. A circular such as that which lies before us defeats its own object, for its arguments are those of a person who has not studied the subject concerning which he writes. Perhaps Dr. Coley would be well advised to moderate the enthusiasm of Mr. Moncrieff.

THE OCULAR FACTORS IN SPINAL CURVATURE.

In the last three years Dr. G. M. Gould of Philadelphia has called attention in a number of papers to the far-reaching ill-effects of eye-strain, while his opinion upon European methods of refraction-testing is known to be highly uncomplimentary. In return several critics of Dr. Gould's theories consider that he sees the result of eye-strain in pathological circumstances where it has no existence. He has lately attributed spinal curvature to eye-strain, and this time his views appear to be in accord with those of other observers. If artificial astigmatism be produced in a normal person with a cylindrical lens at an axis of 75° vision will be obscured unless the head is tilted 15° to the right so as to bring the axis into the vertical line. Then the perception of vertical objects, such as trees, houses, letters of the alphabet, &c., is clearest. Similarly a patient with this astigmatism will tilt his head 15° to the right in order to obtain clear vision. In the *New York Medical Journal* of July 28th Dr. H. Augustus Wilson, professor of orthopædic surgery in the Jefferson Medical College, confirms Dr. Gould's conclusions and reports two cases. In 1900 a boy, aged 14 years, was brought to Dr. Gould with symptoms of eye-strain. The refraction was as follows: in the right eye, – S., 0·25 + C. 5·25, axis 75°; in the left eye, + S., 0·50 + C. 6, axis 75°. There was also spinal curvature. The ametropia was corrected and the patient was referred to Dr. Wilson for the treatment of the spinal curvature. He found functional scoliosis in one long curve extending from the pelvis to the head. The head was inclined to the right. The boy was in the habit of carrying a heavy bundle of newspapers under his left arm, while with his right hand he used to throw and fold the papers. This involved excessive use of the right side. After wearing the glasses for two months and undergoing a short course of exercises the spine became normal. In the second case, a girl, aged 14 years, was seen three years after deformity of th observed by her parents. She presented the usual form of S-shaped scoliosis with rigidity. The head was persistently tilted to the right. She was wearing spectacles which had been obtained from an optician and suffered from migraine. She was sent to Dr. Gould who found that her refraction was as follows: right eye + 0·87 + C. 0·62, axis 75°: left eye + S. 0·5 + C. 1·25, axis 90°. The ametropia appeared to have been at least a factor in the development of the scoliosis, for though the usual gymnastic and manipulative methods secured increased flexibility of the spine and greater muscular development, the head remained tilted to the right until the ametropia was corrected. After wearing suitable glasses for several days the head assumed a more normal position.

THE THIRD CONGRESS OF MEDICAL RADIOLOGY AND ELECTROLOGY.

This Congress, originally fixed to be held in the autumn at Amsterdam, has had its place of meeting transferred to Milan. Professor Bozzolo of Turin, one of the first among European physicians to prove the efficacy of radiotherapeutics in diseases of the circulation, has been chosen president of the organising committee. An adjunct to the Congress, at once novel and instructive, will be the "Esposizione" of apparatus illustrative of radio- and electro-therapeutics, many continental firms being represented in the exhibition rooms. All professional men desirous of assisting at the Congress are requested to communicate with the Secretary, Dr. Carlo Luraschi, 11, Via Sant Andrea, Milan.

THE ICE-CREAM SEASON.

On August 30th and 31st respectively an inquest and a police court summons were heard in London which were complementary the one to the other. The inquest was upon the death of a child, aged eight years, and was held at Stepney. Evidence showed that the child had eaten some ice-cream wafers bought from an Italian in the street. She was attacked with sickness and died on the following day. Mr. N. W. W. Meadows, who attended her, stated that her symptoms were exactly those of cholera. He considered that death was due to exhaustion from epidemic diarrhœa accelerated by eating ice-cream probably made under insanitary conditions. A verdict of death by misadventure was returned. On August 31st at Marylebone police court Angelo Romano, an ice-cream vendor, was summoned by the St. Pancras borough council for failing to take proper precautions for the due protection of the ice-cream sold or stored on his premises from infection or contamination. Dr. J. F. J. Sykes, the medical officer of health, in giving evidence, produced a utensil found on the defendant's premises which was used for the purpose of making up what are called ice-cream wafers. In the corners and angles was a quantity of fermenting and decomposing milk. Dr. Sykes remarked that there had been many cases of ptomaine poisoning in the district and that many children had died from diarrhœa after eating ice-cream. He further stated that anyone partaking of ice-cream taken from the utensil in the condition in which it was found would probably become ill. Mr. Paul Taylor expressed surprise at Dr. Sykes's remark that many children had died from diarrhœa after eating ice-cream, and fined the defendant 20s. and costs, saying that the case showed how important it was that the Act of Parliament should be enforced. So-called ice-cream, which is chiefly made of milk and eggs, is very popular among the poorer classes in hot weather and its method of preparation in many cases is filthy in the extreme. The Act of Parliament is doubtless sufficient if enforced with rigour but the difficulties in the way of inspection are very great. However, the well-known and extremely poisonous effects of dirty ice-cream should stimulate local health authorities to do everything in their power to prevent the manufacture of this sweetmeat under such grossly insanitary conditions as is not infrequently shown to be the case.

A CONTRIBUTION TO THE HISTORY OF MEDICAL LEGISLATION IN NORTH AMERICA.

In the American *Medical Library and Historical Journal* for April, 1905, Mr. Charles Perry Fisher, the librarian of the College of Physicians of Philadelphia, publishes the full text of a Bill which possesses some historical interest. It was entitled "An Act to Regulate the Practice of Physic and Surgery within this Commonwealth:" it had its first reading in the House of Representatives of the Commonwealth of Pennsylvania on March 24th, 1794, and was "ordered to be laid on the table." It was to have been brought up for its second reading on March 31st, but it was not read at that meeting and no further reference to it can be found. Apparently, therefore, the Bill did not become law. It is known, however, that medical legislation in America is of much older date than this, for Dr. Francis R. Packard in his "History of Medicine in the United States," published in 1901, states in the chapter on Medical Legislation in the Colonies that the General Assembly of New York on June 10th, 1760, passed a law regulating the practice of medicine in the city of New York, and that on Sept. 26th, 1772, an Act was passed to "Regulate the Practice of Physic and Surgery within the Colony of New Jersey." The Bill of 1794 consisted of four sections, the second of which provided that unqualified practitioners "shall forfeit and pay for the first offence the sum of fifty pounds ...... and for the second and every subsequent offence shall forfeit and pay the sum of one hundred pounds." One of the clauses stated that the Bill did not prohibit any person from drawing teeth, bleeding, or cupping, or from giving assistance in cases of sudden emergency.

THE PHYSIOLOGICAL ACTION OF A RECENTLY DISCOVERED AFRICAN ARROW POISON.

Dr. Charles Bolton has investigated the toxic properties of an arrow poison which was obtained by Dr. D. Alexander from a medicine-house at Ghasi, a pagan town in Northern Nigeria.[1] According to Dr. Alexander the poison, when fresh, forms a semi-fluid, sticky, black substance; it is smeared on sticks and is scraped off and heated when required for re-dipping the arrows. It appears to contain the juice of a variety of fig, the placenta of which is used in the manufacture of the poison. Dr. Alexander states that he saw a native shot in the abdomen with a poisoned arrow and that death resulted, apparently from failure of the heart, in about 25 minutes. Dr. Bolton dissolved the poison in 0·85 per cent. salt solution for intravenous injection into animals, including cats, rabbits, guinea-pigs, and frogs. He found that the poison selects muscular tissue for its action, but there is no evidence that it produces any action upon the central or peripheral nervous system. It paralyses the voluntary muscles and causes death by a direct action upon the muscular tissue of the heart. The first effect of the poison is to stimulate directly the muscular coats of the arterioles and thus to cause a rise of arterial pressure, with the result that the vagus centre in the medulla is excited, causing a slowing of the rhythm of the heart, together with a fall in the arterial blood pressure. The irritability of the heart muscle is greatly increased and soon the vagus fails to hold it in check: as a consequence the rhythm of the heart is accelerated and the blood pressure therefore rises to a higher level as the inhibition of the vagus is overcome. It is, however, probable that the chief factor in maintaining the high blood pressure is the constriction of the peripheral vessels. The rhythm of the heart becomes more rapid and irregularity appears, the heart finally passing into delirium cordis and ceasing in diastole.

---

[1] Proceedings of the Royal Society, Series B, July 2nd, 1906, p. 13.

THE Huxley lecture will be delivered at Charing Cross Hospital Medical School on Monday, Oct. 1st, as we announce elsewhere. The lecturer for this year is Professor Ivan Petrovitsch Pawlow, professor of physiology in the University of St. Petersburg, who is taking for his subject "Recent Advances in Science and their Bearing on Medicine and Surgery."

THE Semmelweiss memorial which has been erected in the Elisabeth-square of Budapest will be unveiled on Sept. 30th. The ceremony will begin at 10.30 A.M. with a meeting in the hall of the University of Sciences. The memorial itself will be unveiled at midday.

FIRST REPORT OF THE EXPEDITION TO THE AMAZON, 1905.

(From the Liverpool School of Tropical Medicine.)

BY H. WOLFERSTAN THOMAS, M.D. MCGILL,
ASSISTANT LECTURER, LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

FOR the purpose of investigating the distribution of disease, and in particular of yellow fever, along the Amazon the expedition left its headquarters at Manaos, Brazil, and proceeded up the river. Iquitos, in Peru, was reached on Dec. 31st, 1905. A stay of three months was made there and a report, embodying the results of observations made during that period, has been drawn up for presentation to the Peruvian Government. The present communication is an abstract of that report.

The town of Iquitos lies along a high bank overlooking the river Maranon. Along the river front are situated the municipal buildings and the chief business houses. Parallel with the front road is the Calle de Prospero; on it are most of the shops. Numerous streets intersect it; these run from the river front back to the swamps and on them are situated most of the private residences. As Iquitos has increased in population the town has extended up and down along the river bank but the tendency appears to be to extend backwards in the direction of the swamps. The richer class occupy the closely-built central part of the town; the poorer class tend to congregate in settlements on its outskirts. The better class live in well-built houses; the poorer inhabitants in cane- or mud-walled huts. The roads are in a wretched state; they are undrained, full of ruts and holes, and in wet weather become almost impassable. Iquitos, especially along the river bank and near the swamps, is noted for the number of its mosquitoes. Houses near the river front are never free from these pests and unless wire screens are used the situation becomes intolerable after dusk. The poorer class store no water on their premises; it is brought as it is needed from neighbouring springs, and as a result mosquito larvæ were never found in their houses. 69 houses belonging to persons of the better class were examined. In 63 of them stegomyia fasciata was breeding; in six larvæ of culex were found. Neither water reservoirs nor privies are protected from mosquitoes by wire netting; stegomyia and culex were frequently found breeding in both. As is usual, stegomyia was found to breed freely in the various discarded pots and pans, bottles and barrels which invariably accumulate about tropical establishments. In the yard attached to one house were 16 large barrels, nine tubs, seven large oil cans, a large heap of empty tinned meat cans, and a collection of nearly 300 bottles. All were stored so as hold a little water. 90 per cent. of them contained larvæ of stegomyia fasciata. This house was noted for the number of its mosquitoes and at one time several deaths from "vomito negro" had occurred there. A general cleaning up of the yard was advised and all the disused barrels were stored end upwards. A marked diminution in the number of mosquitoes immediately resulted. The better class, educated and richer people, are therefore largely responsible for the large numbers of stegomyia fasciata existing at Iquitos. Nearly all the municipal and public buildings are sources for the propagation of culicidæ. Culex bred freely in the stagnant water of overgrown or chocked ditches, in pools of rain-water, and in holes along the river's bank. Larvæ of stegomyia were very rarely seen in these situations. Anopheles bred chiefly in the swamps near the town.

A general survey of the public health of Iquitos was made. Iquitos is, comparatively speaking, well situated and the better class are well housed, but the maintenance of the town is bad and the poorer class particularly live under unhygienic conditions. Drains are for the most part bad and usually consist of mere trenches cut in sandy soil; a few are constructed with cement bottoms and sides. None are properly maintained and they are consequently often blocked. In the poorer quarter there is hardly any attempt at drainage. There is no public water-supply; water for drinking is obtained from various springs or from rain-water stored in cisterns sunk in the ground. There is no adequate system of sewage disposal; badly designed and improperly maintained privies are frequently employed. The poorer classes of the inhabitants defæcate indiscriminately in every part of the town; as a result fæcal contamination of drinking water is common. Bacilli coli communis and eggs of ankylostoma duodenale were frequently found in water currently used for this purpose. There is no system of garbage disposal; household refuse is deposited almost anywhere.

Notwithstanding these insanitary conditions Iquitos is not an exceptionally unhealthy place. The prevailing diseases from January to the end of March, 1906, were whooping-cough, measles, bronchitis, and infantile diarrhœa amongst children; gastritis and gastro-enteritis, bronchitis, and malaria amongst adults. Other diseases seen were leprosy, amœbic dysentery, tuberculosis in various forms, and one case of epithelioma. Syphilis and gonorrhœa are very prevalent and are being disseminated along the rivers by launchmen and peddlers. The expedition had hoped to see cases of the "vomito negro" of Iquitos. This disease has a high mortality and is locally considered to be distinct from yellow fever. No cases of it or of yellow fever occurred during the stay of the expedition at Iquitos. It seems, however, probable, from information given by local medical men, that they are one and the same disease.

To obtain some idea of the prevalence of malaria amongst the general population 764 persons were examined. In the blood of 98 the "malignant tertian" type of malarial parasite was found. The majority of those infected were Indians and men employed in launches along the rivers. Only two were infected amongst 97 school children between the ages of four and 14 years examined at Iquitos. The hæmoglobin of these persons was examined at the same time as their blood. The low average amongst children, Indians, and the poorer classes was exceedingly striking, since it varied between 45 and 72 per cent. The blood of the better class showed a higher average, varying between 72 and 80 per cent. The explanation of this marked anæmia is believed to be ankylostomiasis. Practically all the native children are infested with this parasite. An accompanying infection with ascaris lumbricoides or various tæniæ was frequently observed.

The following diseases were observed amongst domestic animals at Iquitos. In cattle piroplasmosis, malignant œdema, and perhaps quarter evil. Trichinosis was seen in swine. Amongst poultry occurred chicken cholera and fowl diphtheria. Trypanosoma Lewisi was observed in rats.

From the data at our disposal we conclude: 1. That the town of Iquitos is relatively free from malaria and that the majority of cases occurring there have become infected in the rivers adjacent to Iquitos. 2. That ankylostomiasis is present and widespread amongst all classes; that the infection is spreading chiefly by reason of the unhygienic disposal of fæcal material. 3 That diseases other than gastric disturbances, dysentery, malaria, measles, and whooping-cough, are comparatively rare; that syphilis, gonorrhœa, and tuberculosis are now attacking the Indians. 4. That the present surface sewers are quite unable to drain the town properly. 5. That an adequate water-supply is urgently required. 6. That more rigorous sanitary laws are needed; that the sanitary department should extend its powers so as effectively to deal with (a) the removal of night soil; (b) removal of garbage; (*c*) prevention of the pollution of the springs; (*d*) prevention of the committing of nuisances; (*e*) the compelling of all householders to screen receptacles for storage of water, &c., to prevent mosquitoes propagating; and (*f*) a more thorough meat inspection and the prohibition of the indiscriminate slaughtering of animals outside the slaughter-house. 7. That a public hospital is greatly needed.

In the original report means of realising the desired improvements are suggested in detail.

Manaos, May 12th, 1906.

GLYCERINATED CALF LYMPH.

WE have received for publication the following Preliminary Report to the Local Government Board on the Results of Sustained Subjection of Glycerinated Calf Lymph to Temperatures below Freezing Point, by Dr. Frank R. Blaxall and Mr. H. S. Fremlin:—

These experiments were in the first instance undertaken to determine whether the active agent of vaccine lymph could withstand, without loss of potency, temperatures below the freezing point. Afterward they were directed to ascertain whether sustained subjection of glycerinated calf lymph to a temperature 5° (Centigrade) below freezing point could be utilised as a means of maintaining a reserve and store of lymph without risk of loss of its specific activity. General experience and numerous special experiments have shown that the agents most productive of weakness and failure in glycerinated lymphs are age and heat. Thus, the active "vaccine" agent present in crude lymph when collected from the calf loses its potency if subjected for five minutes[1] to a higher temperature than 57·5° C. Again, glycerinated lymph becomes vaccinally inert if kept at 37° C. for more than 36 hours. Similarly, the extraneous micro-organisms apt to be present in glycerinated lymph are eliminated the more quickly the higher the temperature to which the lymph is exposed.[2] At 37° C., for instance, their elimination is accomplished in 36 hours or less; contrariwise, at 10° C., and at lower temperatures, their elimination is very slow. It was anticipated therefore that if the everyday deleterious influence of heat on lymph could be neutralised, such tendency to loss of activity—which in present conditions is associated with "age" of lymph—might be greatly mitigated and a method of storing glycerinated lymph with full preservation of its potency thus obtained.

Our first experiments were commenced in January, 1900, with "freezing mixtures." Samples of glycerinated lymph contained in small test tubes hermetically sealed were placed in a mixture of ice and salt. The temperature to which the tubes were thus subjected was found to range in practice from 9° below to 10° above zero Centigrade; and no means being at hand of obtaining a low, and at the same time stable, temperature, the samples were at the end of a week withdrawn from the "mixture." These samples were then tested on calves, side by side with other samples of the same glycerinated lymph which throughout the experiment had been kept in an ice chest at 10° C. Excellent vesicles were developed by both sets of samples showing that the vaccine organism had not suffered any impairment of potency by an exposure of uncertain duration to a temperature of − 9° C.

Our second experiment was to subject samples of glycerinated lymph to a much lower temperature—namely, that of liquid air which is the equivalent of −180° C. This we were enabled to do by the courtesy of Dr. Macfadyen and Mr. Rowland of the Lister Institute. Samples from four glycerinated lymphs were placed in leaden capsules each holding about three cubic centimetres and these were inserted in a vessel containing liquid air, companion samples of the same glycerinated lymphs being kept as controls in an ice chest at 10° C. At intervals of one, two, three, five, and 11 weeks the samples were withdrawn from the liquid air for the short time necessary for allowing capillary tubes to be charged from them, similar procedure being adopted with the corresponding samples in the ice chest. These capillary tube samples of the lymphs were forthwith tested on calves to ascertain whether their potency had been affected. At the end of 11 weeks exposure of the samples to liquid air ceased but the experiment was prolonged by further storage, alike of experimental and control samples, in an ice chest at 10° C. for an additional 15 weeks with a view to testing from time to time and at the end of that period samples of both sorts on calves.

The results of the inoculations of the samples on calves were as follows. Up to 11 weeks the limit of the period of subjection of samples to the temperature of liquid air both sets of samples gave equally good vesicles on calves; no difference was distinguishable between them. Thus, sustained exposure to the temperature of liquid air for near upon three months had in no way impaired the potency of the glycerinated lymphs. On the other hand, the results obtained with the two sets of samples after the additional storage for 15 weeks at 10° C. were very different. Those samples which had in the first instance been exposed to the temperature of liquid air continued, after 15 weeks' additional storage at 10° C., to yield good vesicles on the calf, whereas the control lymphs yielded, after further keeping in like fashion, only poor vesicles or were quite inert. It appeared, indeed, that advantage had accrued to those sections of the glycerinated lymphs which had been subjected for 11 weeks to the temperature of liquid air.

Our third experiment was on a larger scale. It consisted in placing glycerinated lymph for a year in a "cold storage depôt" in London, in which the temperature was held to be maintained with great regularity at 23° F. or − 5° C. Samples from 92 glycerinated lymphs were taken for test in this sense. These samples at the date of the experiment varied greatly in age; the oldest was eight months and the youngest 16 days from the date of collection. Two samples, each consisting of about one cubic centimetre of emulsion, were taken of each lymph; and these were placed in separate small test tubes, corked and sealed. Each such test tube was then placed in a wooden case and this case was tightly corked. One set of 92 samples was placed in a sealed package and inserted in the cold store depôt on Oct. 3rd, 1902, and the other (companion) set, on the same date, was placed in an ice-chest at 10° C. in our laboratories. There they remained in each instance for one year. On Oct. 2nd, 1903, these packages were withdrawn from cold store and from ice-chest and their contents were examined. All the samples which had been stored at − 5° C. were in good condition but in the case of many of those which had been stored at 10° C. the emulsion had to a considerable extent soaked away or dried up. The several samples were now tested for potency on calves, inoculations being made on three separate occasions on these animals within a period of three weeks, the samples being meanwhile stored at room temperature. On each occasion each "cold store" sample was tested side by side with its companion ice-chest sample, on one and the same calf. As a result the "cold store" lymphs yielded 91·4 per cent. "insertion success," whereas the "ice chest" lymphs yielded no more than 16·2 per cent. (See Table I. annexed.) It deserves to be noted, moreover, that the failures with the "cold store" lymphs occurred only when these having been three weeks removed from the store had been further kept at room temperature. It was observed, too, that the vesicles yielded on the calves by the "cold store" lymphs were of better appearance and quality than those yielded by the "ice-chest" lymphs.

A fourth experiment on the same lines was made with 91 glycerinated lymphs. Two samples of each, taken as before, were placed in small glass test tubes, which were then corked and sealed, and each such test tube was in turn packed in a wooden case duly corked. On this occasion each set of samples was in addition inclosed in a tin box, the lid of which was soldered on, so that the box was hermetically sealed, the purpose being to obviate, if possible, the drying up of emulsions such as had occurred in the third experiment in the case of samples stored in the ice-chest. Of these 91 glycerinated lymphs the oldest at the date of the experiment was 13 months from the time of collection and the youngest nine days. The tin boxes remained respectively in the cold store at −5° C and in an ice-chest at 10° C for a whole year, at the expiration of which period the boxes were withdrawn and the contents examined. As before, the samples which had been in the cold store were found in good condition, and on this occasion drying up of those which had remained in the ice chest at 10° C. had to a considerable extent been checked, if not entirely prevented. All the samples were inoculated on calves, in the same way as before, on three occasions, the last inoculation being made 32 days after removal of the tin boxes from the cold store and from the ice-chest respectively, the samples having been kept after removal from the tin boxes meanwhile in an ice-chest at 10° C. As a result of inoculation of calves the "cold store" lymph yielded 98·9 per cent. and the "ice-chest" samples 41·8 per cent. insertion success. And, as before, it was noted that the vesicles yielded by the "cold store" samples were of better appearance and quality than those yielded by samples from the "ice-chest" (see Table II. annexed).

---

[1] Medical Officer's Report to the Local Government Board, 1900-01, p. [illegible]

[2] Medical Officer's Report to the Local Government Board, 1902-03, p. [illegible]

The above two series of experiments showed definitely enough that, as tested on calves, cold storage of glycerinated lymph for a year at –5° C. prevents that deterioration and loss of potency which commonly occurs to lymph stored at the higher temperature 10° C. Bacteriological examinations were made of all these samples at the time of withdrawal from the cold store at –5° C., and ice chest at 10° C. respectively. The results showed that storage in glycerine for a year or more, whether at –5° C. or 10° C., serves to practically eliminate the contained extraneous organisms. At this stage, therefore, it was sought to ascertain the effect of the cold storage treatment on lymph subsequently employed in human vaccination. For this purpose 14 glycerinated lymphs contained in small scaled test tubes were packed in a hermetically closed box, placed in the cold store at –5° C. and were retained there for four months and 23 days. When withdrawn these lymphs were examined and tested for potency in the usual way. These preliminary tests having proved satisfactory the 14 lymphs were issued to public vaccinators on an average 19 days after removal from the cold store. Employed by public vaccinators in the vaccination of 16,771 individuals they gave a percentage success of: case, 98·8; insertion, 94·2; slightly higher figures than the average success-rate obtained in the preceding year with the current lymph of the establishment—viz., 98·4 per cent. case, 93·5 per cent. insertion, success. The current lymph of the previous year had been at the time of issue "aged" one month *to two months*, so that the cold store lymph in spite of its greater age gave higher percentage results than the lymph ordinarily issued.

From these experiments it would appear: 1. That in glycerinated lymph the active agent of vaccine not only can withstand freezing but can survive a temperature 180° C. below freezing point for a considerable time and this without loss of potency. 2. That glycerinated lymph can be retained in a cold store at –5° C. for a year without diminution of its potency, whereas glycerinated lymph, stored at 10° C. for a year, parts with its activity to an uncertain but considerable extent. 3. That sustained subjection to cold appears to be in no sense hostile to the active agent of vaccine; that, on the contrary, lymph thus dealt with was capable of producing excellent vesicles on calves and that the results obtained with it in human vaccination were wholly satisfactory.

F. R. BLAXALL.
H. S. FREMLIN.

THE FORTHCOMING ELECTION OF DIRECT REPRESENTATIVES FOR ENGLAND AND WALES TO THE GENERAL MEDICAL COUNCIL.

WE have received the following circular with a request for its publication:—

To the Chairmen of the Divisions of the B. M. A. in England and Wales.

27, Wimbledon Park-road, Wandsworth, S.W., 1st September, 1906.
Telephone · 631 Battersea.

DEAR SIR,

ELECTION OF DIRECT REPRESENTATIVES FOR ENGLAND AND WALES TO THE GENERAL MEDICAL COUNCIL, 1906.

As you are probably aware the scheme prepared for the nomination through the British Medical Association of candidates for election to the G. M. C. this year has been abandoned. There seems, however, to be no reason why there should not be an organised attempt to return three medical practitioners who would prove acceptable to the majority of the profession as their representative on the G. M. C. In order to do this it becomes necessary for some one to take the initiative. I would therefore submit for the consideration of the members of the profession within the area of your division the following broad suggestions and would ask you (as the time is short) to be good enough to consult them by means of a meeting to be held before the 15th October under the auspices of your division. The suggestions are these:—

1. That as the time is short and only three are to be elected, no territorial arrangements be attempted.

2. That the whole of the local profession be asked to attend your division meeting. This could be done by inviting them to a scientific paper and discussion, and the question appearing as an item on the agenda. A copy of this circular could be sent if it were thought desirable.*

3. That each agenda do contain the names of all candidates known of up to date (see list at end of letter).

4. That this list of candidates is not to be limited to those who were nominated by the divisions of the Association.

5. That at each such meeting those present do vote. Each to have three votes. No plumping allowed. The chairman, who shall be scrutineer, with one other to be elected at the meeting, shall place against each candidate the total number of votes he has obtained, and post this list as provided in Clause 6.

6. That these lists be sent on or before Saturday, 20th October, to Dr. Hugh Ker, President of the Metropolitan Counties Branch and late resident in Birmingham district, who has kindly consented to act as scrutineer with Dr. Bateman (Medical Defence Union) and Dr. Hugh Woods (Ldn. & C. M. P. Society). The address is Tintern, Balham-hill, London, S.W. The envelope to be marked "*General Medical Council.*"

7. That those three candidates who have the highest aggregate total of votes be considered the candidates preferred and to be recommended to the profession. Each area participating shall at the meeting held to consider the list also pass a resolution to support in all ways possible these three whoever they may be (e.g., by addresses, by notices on all agendas, post-cards, &c., issued, &c. &c.).

8. These three names with their addresses will be sent for publication to THE LANCET and *Journal* on October 27th. The agenda calling the meeting could give this information in advance; and thus save subsequent circulars.

I append a list of those who are known to be candidates and have placed them in alphabetical order. I would explain that the divisions of the British Medical Association seem to offer the necessary local machinery for the above object, and this is the sole reason for availing ourselves of their aid. The union of the profession is our great object. I feel sure I need hardly add that I hope this communication will be considered by no means a dictation but rather an attempt to coördinate the profession in the consideration of a matter of vital importance to itself and trust you will cordially approve and support it. A similar attempt has lately been made in London to obtain the wishes of the profession as to certain candidates. No steps were taken to withdraw any candidate who was standing. A selection was made; every member was duly advised of the choice and the result was eminently satisfactory. No pledges whatever were asked or given. After the publication of the three names heading the list these candidates would be justified through their own committees or alone to take any advantage of the voting they considered desirable. There can be no expectation of a unanimous response to the scheme this year. I would only suggest that, as I am informed it will meet with the ready acceptance of a large number of the profession, we can hope that at future elections they will look to something similar as best suited to voice their wishes, and as a ready means by which to influence the indifferent members of our profession to vote for candidates generally recommended.

Believe me, yours faithfully,
LLEWELLYN WILLIAMS, Chairman,
Wandsworth Division, British Medical Association.

P.S.—If you decide to do what you can in the matter during the short time at our disposal, would you kindly send me a post-card, so that some idea may be formed of the progress being made.

List of candidates known.—G. H. Broadbent (Manchester), Geo. Brown (Cornwall), Langley Browne (West Bromwich), J. F. Bullar (Southampton), Andrew Clark (London), A. Godson (Cheadle), Geo. Jackson (Plymouth), H. A. Latimer (Swansea), L. S. McManus (London), J. Rutherford Morrison (Newcastle-on-Tyne), C. J. Renshaw (Ashton-on-Mersey), J. M. Rhodes (Manchester), F. J. Smith (London), J. Smith (Chiswick), C. R Straton (Salisbury).

* Copies of this circular can be obtained if ordered of me before Sept. 15th at the rate of 2s for every 50, or part of 50: if a large number were ordered the benefit of the printer's reduction could be obtained and money returned.

ENTERIC FEVER IN INDIA.

APPOINTMENT OF A STANDING COMMITTEE.

THE Standing Committee appointed by the Government of India to consider the prevalence and prevention of enteric fever in India held its first meeting on July 31st and subsequent days in the United Service Institute, Simla. The following officers who constitute the committee were present: Surgeon-General W. L. Gubbins, C.B., M.V.O., V.H.S., A.M.S., principal medical officer, His Majesty's forces in India (president); Lieutenant-Colonel J. T. W. Leslie, I.M.S., sanitary commissioner with the Government of India; Colonel R. H. Forman, R.A.M.C., principal medical officer, Bombay Brigade; Colonel D. Ffrench-Mullen, I.M.S., principal medical officer, Sirhind and Jullundur Brigades; Lieutenant-Colonel T. P. Woodhouse, R.A.M.C.; Lieutenant-Colonel D. Semple, R A M.C. (retired), director of the Central Research Institute of India; Captain Greig, I.M S., on special duty, Central Research Institute of India; Captain L. W. Harrison, R.A.M.C.; Captain E. Blake Knox, R.A.M.C. (secretary); Captain A. B. Smallman, R.A.M C.; and Lieutenant E. J. H. Luxmoore, R.A.M C. Major A. R. Aldridge, R.A M.C., sanitary officer, Army Headquarters, was also present as expert in army sanitation.

His Excellency the Commander-in-Chief (Lord Kitchener) opened the meeting and in the course of his address made the following remarks: "I have thought it necessary to form this Standing Committee to advise us in our efforts to reduce the amount of enteric fever among the troops in this country and to coördinate the work of the whole medical profession, both civil and military, in this direction. It is hardly necessary for me to tell you that the three principal diseases the ravages of which cripple our troops are *malaria*, venereal, and enteric fever. I am glad to say that with regard to the two former we have made very successful progress in limiting the evil but when we come to enteric fever we are still, I am afraid, very much where we were. Last year we had no less than 1146 admissions and 213 deaths from this disease. This is an improvement on the record of 1904 but I regret to note that during the current year up to the end of June we had already 513 admissions and 126 deaths from this cause. It is evidently the duty of every one of us to fight enteric fever in every possible way. The ravages of cholera, the curse of the army in India in days gone by, are now happily a reminiscence of the past, and if we consider enteric fever as a no less dangerous disease than cholera, and are equally energetic in stamping it out, I have great hopes that we shall succeed eventually in bringing this scourge in its turn under control. We know that the time when young soldiers are most subject to enteric fever is on their first arrival in this country and subsequently at certain seasons of the year when a prevalence of the disease may be annually anticipated. The general lines on which we should work are, I think, fairly clearly defined but the details of elaboration form, it appears to me, the crux on which I hope your advice and efforts will be of the greatest assistance to us in dealing with this most insidious disease. I may briefly suggest as the main outlines for our action: (1) sanitation of cantonments and barracks; (2) isolation of enteric patients; (3) detection of the origin of an outbreak or of a single case; (4) inoculation; and (5) blood examination. On the subject of sanitation a great deal has been written and the success which has resulted from much practical work has proved what good results can be achieved in this direction. Ambala, for instance, has during the last 12 months been an instance of the good fruit which care and forethought, combined with attention to detail, can produce, and in many other places we have evidence to convince us that our efforts are not in vain. Of course, sanitary reform means the expenditure of money, but money will not be wanting for this object if we can be certain that we are working on the right lines. I will not enter into the much discussed question of the propagation and conveyance of the enteric germ through the medium of water, flies, dust, &c. These are evidently all means of infection, each in their degree, and measures for neutralising their pernicious influence must therefore be taken. In this connexion I will lay on the table for your consideration an able paper on the Sanitation of Cantonments, recently written by Colonel Thornhill. As regards the isolation of enteric patients and those who have been associated with them, I believe the importance of this precaution is now more fully recognised and enforced than used to be the case. All clothing and excreta must, of course, be most carefully disinfected. The detection of the origin of outbreaks of enteric fever is a question of the gravest importance, but it is also one of great difficulty. More than once, however, conspicuously successful results have ensued when immediate and careful deductions have been persistently followed up. All cases of slight fever should be viewed with suspicion and the patient sent to hospital for diagnosis. Early diagnosis is an absolute essential, for it allows of early prophylactic measures being enforced. No efforts should be spared to ascertain the origin of an outbreak, or even of a single case, for on the correct results of such inquiry depend success or failure in preventing recurrence. Commanding officers and the whole military machinery of the unit should be associated with the medical officer in the search for the originating cause and the precautions to be adopted to prevent the spread of the disease should be at once communicated to all concerned. Full use should be made of blood examination in following up any clue that may be found. I now come to the important subject of inoculation. You are doubtless aware that we have for some time past been engaged on experiments in India in antityphoid inoculation and I am glad to say that great advances have been made on the old system which prevailed at the time of the South African war. By antityphoid inoculation we can assist the soldier's tissues to resist the disease by providing him with fluids in the blood which react on, and cause disastrous results to, any bacterial invasion by typhoid germs. That by this means we can obtain fruitful results in India is proved by recent experience. Take the 17th Lancers, for instance. This regiment landed in India on Sept. 28th, 1905. The total number of enteric fever cases from that date to June 15th, 1906, has been 61, of whom 11 have died. Of these 61 cases two only had been inoculated and both recovered. 150 officers and men of the regiment were inoculated. The value of inoculation in other cases has been equally proved. But though we have in inoculation a possible solution of this grave question, I wish to point out to you, gentlemen, that this method of treatment is still comparatively in its infancy, and though we have, I think, sufficient data to justify us in introducing the system generally into this country, I look forward to great improvement in its operation being arrived at in the near future through the devoted and untiring energy of the professional experts in the subject, both in India and at home. I further anticipate that careful investigation and practical experience will lead us still further on the path towards doing away with some of the drawbacks which now attend the process. I have placed blood examination last, though I have referred to it before as an important factor in following up any clue to the discovery of the cause of an outbreak. We all, I think, realise that many men may, though apparently quite well, be carrying about the germs of enteric fever in their blood, and thus become the means of transferring the disease to others. This is often the case with convalescents from enteric fever, even after a considerable period of isolation, and I consider that blood examination will therefore be of immense value in indicating to us where precautions are necessary and where our preventive efforts should be directed. As a layman I can only suggest these views for your consideration as experts, and I will now leave you to the consideration of the details of this most important subject, with the assurance that your views and opinions will be received by me with the greatest interest and in the confident anticipation that by following the practical lines which you may eventually suggest we may take an important step forwards towards stamping out enteric fever among our soldiers in India."

The committee then passed to consider carefully enteric fever with reference to its prevalence amongst various classes of individuals and communities in India. Statistics and evidence from the Army Medical Reports, the Annual Reports of the Sanitary Commissioner and others from the year 1856 being placed before it. The various sources of infection, excreta, fabrics, food, drink, &c., were then carefully considered and discussed in every detail and lines of present prophylaxis and a campaign for future prevention were laid down. In the matter of cantonment sanitation the committee had the advantage of the presence of the *Inspecting Officer of Cantonments (Lieutenant-Colonel* Thornhill, C I E.) whose views on this matter were of great assistance. The subject of antityphoid inoculation was fully dealt with. It is hoped that the decisions arrived at and the line of action laid down will have marked beneficial results not only to the health of the army but also to the community at large The committee after five full days' sitting adjourned until the middle of October when reports on the practical working of its various resolutions will be further examined and, if necessary, added to.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 6th, 1828.

THE REPORT of the Select Committee on Anatomy is an interesting, and, upon the whole, a satisfactory document. Mr. WARBURTON is especially entitled to the thanks of the profession and of the public for the zeal and ability which he exhibited as Chairman of the Committee; and although a wider scope might, perhaps, have been beneficially given to some branches of the inquiry, we are not on that account the less disposed to acknowledge the value of what has been effected by the labours of the Committee. ……

There is a part of SIR ASTLEY COOPER'S evidence, which is likely to have a stronger influence than any arguments which can be urged in favour of an alteration of the law, towards inducing persons of a certain intellectual calibre, to support any measure which may have the effect of putting an end to the practice of exhumation The worthy baronet has not hesitated to declare that there is no person, however exalted his rank, whose body, if he were disposed to dissect it, he could not obtain.

"Does the state of the law actually prevent the teachers of anatomy from obtaining the body of any person which, in consequence of some peculiarity of structure, they may be particularly desirous of procuring?—The law does not prevent our obtaining the body of an individual if we think proper; for there is no person, let his situation in life be what it may, whom, if I were disposed to dissect, I could not obtain.

"If you are willing to pay a price sufficiently high you can always obtain the bo[illegible]—The law only enhances the price, and does not [illegible] nobody is secured by the law, it only adds to [illegible]

This declaration is well calculated to produce an effect on the fears of persons to whose understanding reason could find no access. We shall have frequent occasion to return to the Report, and to the Minutes of evidence taken before the *Select Committee.*

---

* We have given Sir Astley credit for what, we presume, he meant to say; but it is evident that the worthy baronet has with his wonted felicity of diction, made his throat appear rather to the living, than to the dead.

THE

BRITISH MEDICAL ASSOCIATION.

MEETING AT TORONTO.

(FROM OUR SPECIAL CORRESPONDENTS.)

THE seventy-fourth annual meeting of the British Medical Association commenced at Toronto on Tuesday, August 21st, under the presidency of Dr. R. A. Reeve, Dean of the Medical Faculty of the University of Toronto. This is the second time on which the Association has met in Canada, and the second time the place of meeting has been outside the British Isles, the other occasion being the meeting at Montreal in 1897. By Monday Toronto was beginning to get full of medical men from the United States, who are present in large numbers, while not a few members of the medical profession from Montreal, Quebec, and more out-lying provinces and cities of the Dominion had arrived. But the bulk of the travellers from England, Ireland, and Scotland did not arrive until the actual day of the opening ceremony. On the morning of Tuesday it was estimated that about 800 medical men had assembled, but by the time the proceedings of the congress were in full swing over 2200 members of the Association and accredited visitors were present. India, South Africa, Egypt, Australia, and the West Indies are all represented, while there are also visitors from Germany, and, as might be expected in Canada, from France. Many of the visitors from the mother country travelled by the Allan Line steamer *Ionian* and the Canadian Pacific Line steamer *Empress of Britain*, and on both vessels a most comfortable passage was enjoyed.

The choice of Toronto for the place of meeting was a distinctly happy one. The enthusiastic loyalty of the Canadians, their whole-hearted devotion to the mother country, and their more than justifiable pride in their own, with its vast extent and its great resources, perhaps nowhere find more open expression that in Toronto. Toronto strikes the visitor as the most English city in the Dominion in sentiment, but in outward appearance it is characteristically transatlantic. With a population of 262,749 it covers an area of 18½ square miles, possessing an extensive front to the lake. Its streets are for the most part wide and, with the exception of the most busy ones, well wooded, giving a peculiar charm to them, while there are no less than 25 public parks with an extent of 1640 acres. There is an excellent service of electric street cars which on some of the principal thoroughfares run almost continuously, so that it is easy to get from one part to another. Its public buildings are large, handsome, and in many cases beautifully situated, as pictures have recently shown in THE LANCET when illustrating the edifices connected with the Medical School. Toronto forms the meeting place of the two great trunk railway lines of Canada—the Grand Trunk and the Canadian Pacific, while a third great transcontinental railway line is in process of construction. It is consequently a great centre for travellers of all sorts.

The great influx of visitors, both from Canada and the United States, as well as the extra number of people visiting the city in connexion with the Annual Canadian Exhibition which opens on Monday, August 27th, combined to render the principal hotels full to overflowing, but a large number of those taking part in the meeting of the Association have either been entertained by private hospitality or most comfortably housed in some of the residential colleges near the University.

An informal dinner was given by the President-elect, Dr. Reeve, in the University dining hall on Monday, August 20th, to meet the Lieutenant-Governor of the Province, Mr. William Mortimer Clark, K.C., LL.D.

A number of the sections, which are all located in the University and its constituent buildings, held preliminary committee meetings on Monday with the view of arranging their programmes, a very necessary and useful precaution when the mass of material set down for discussion is remembered. There will doubtless be many disappointments, as some valuable contributions have been taken as read, but that was unavoidable.

The inaugural ceremony of the Association took place in the afternoon of Tuesday in the New Convocation Hall of the University, and was in all respects a successful and imposing function. The meeting opened with prayer by the Rev. Principal MacLaren, the head of Knox College, after which a valedictory address was delivered by Mr. G. C. Franklin of Leicester, the retiring President. Dr. Reeve, introduced by Mr. Franklin, was then installed as President, Dr. F. N. G. Starr, the local secretary of the Association, presenting him with the badge of office. Various notable visitors were then received, the Mayor of Toronto, Mr. J. Coatsworth, extending a hearty welcome in the name of the city to all her guests. Professor Irving Cameron, Professor of Surgery in the University of Toronto, Dr. Alexander McPhedran, President of the Canadian Medical Association, and Dr. George A. Bingham, President of the Ontario Medical Association, joined in the words of welcome of the mayor. Sir Thomas Barlow, Sir Victor Horsley, and Mr. Franklin were then made vice-presidents for life of the Association. The presidential address which was then delivered contained an able review of the progress of medicine during the last decade. The President said that the credit for the success attending the second visit of the British Medical Association to Canada must rest largely upon those who have given valuable help in various ways. It had been, indeed, a labour of love to bring from their posts of duty in the old homeland the select and the elect of the profession. The gathering was in a sense a cosmopolitan one. International comity had always prevailed in the profession; disease knew no distinction of country or race and was the common lot of humanity. In the face of an ubiquitous foe it was natural that the confraternity of the healing art should be undivided. He then gave an outline of the early history and progressive development of the British Medical Association, after which he proceeded to review recent advances made in medical knowledge, with special reference to Pawlow's investigations on the process of digestion, and the views expressed by Professor Chittenden of Yale University in his treatise on "Physiological Economy in Nutrition." He pointed out that the question of nutrition concerned all mankind, and said that when the teachings of physiological laboratories and college halls became common property there would be more plain living and high thinking, as well as less repining on the part of the masses, who were now aggrieved on account of their enforced moderation. It was the prerogative of the medical profession to show that nature's laws, rightly interpreted and adopted, were the only safe rule of life, and that much of the money spent on patent foods and so-called patent medicines was misspent. An ample supply of clean pure milk was a very great boon to a community, and service in keeping this question before the public had been done by the pediatric societies in the United States. The marked increase in the debt which medicine owes to physiology and physiological chemistry was acknowledged, and attention was called to the increasing recognition of the value of preventive medicine.

The meeting, the first general meeting of the Association, was then adjourned until the evening, when Dr. W. S. A. Griffith delivered the Address in Obstetrics.[1]

In the afternoon of Tuesday a huge reception was held at Government House by the Lieutenant-Governor of Ontario, who had issued upwards of a thousand invitations. On the same afternoon Professor Goldwin Smith, the famous and veteran historian and scholar, who resigned his professorship of history at Oxford 40 years ago and who for the past 35 years has resided in Toronto, gave a small reception at Toronto Grange to some of the best-known members of the Association. In the evening of the same day the President gave a large garden party in the quadrangle of University College. This form of reception was a novelty and a particularly happy idea, for Toronto was enjoying a spell of very hot weather when the meeting began, and it was inexpressibly pleasant to be able to congregate in the grateful cool of the evening air. An important dinner was also given by Dr. H. A. Bruce on the same evening.

The principal event of Wednesday, apart from the Address in Medicine by Sir James Barr[2] and the Address in Surgery by Sir Victor Horsley,[3] was the luncheon given by the Ontario branch of the Dominion Temperance Alliance to Sir Victor Horsley, Professor Sims Woodhead, and other prominent supporters of teetotal principles. 500 persons sat down to luncheon in the University Gymnasium. The temperance feeling is very strong in Canada and Sir Victor Horsley's assertion that the medical profession at home displayed the same hostile attitude towards alcohol as was shown by the guests of the Temperance Alliance was received with applause, though the statement would hardly have received the endorsement of the British Medical Association. Professor Sims Woodhead, who spoke in sequence to Sir Victor Horsley, appealed to the younger medical men to study the question for themselves, adding that all laboratory work went to show that the use of alcohol interfered with the condition of immunity.

A storm burst over the city on Wednesday afternoon and somewhat marred the reception given to members of the Association at the Toronto General Hospital by the trustees of the hospital. The rain unfortunately compelled the holding of the reception indoors; but some 350 guests made a visit of inspection to the wards. The cupola of the Grace Hospital was struck during the storm.

The annual dinner of the Association was held on Thursday night in the Victoria Rink, Huron-street, under the chairmanship of the President. Dr. Reeve, who was supported by the Lieutenant-Governor of the Province and Professor Goldwin Smith. Some 450 members of the Association and guests were present. In reply to the toast of "The King" the Lieutenant-Governor referred with warmth to the inexcusable ignorance which he said prevailed in Great Britain as to Canadian affairs. The toast of "The British Medical Association" was proposed by Professor Goldwin Smith in eloquent terms, his allusion to the service done to the world by the medical profession in the prevention of empirical murder being received with loud applause. The toast was acknowledged by Sir William Broadbent, other speakers being Sir James Grant, M.D., K.C.M.G., Mr. E. B. Osler, M.P. (elder brother of Professor William Osler of Oxford), Sir William Hingston (the eldest member of the British Medical Association in Canada), Professor Aschoff of Marburg, Dr. Lapicque of Paris, Dr. Mayo of Rochester, Minnesota, Dr. F. W. Mott, and Sir Victor Horsley.

[1] THE LANCET, August 25th, p. 470.

[2] THE LANCET, August 25th, p. 473.

[3] THE LANCET, August 25th, p. 481.

On the same day a luncheon was given by the Empire Club in the clubhouse of the Royal Canadian Yacht Club on Toronto Island. The weather, in spite of a recurrence of thunderstorms, was bright and clear. Some very interesting speeches were made, the note of one and all being that the links binding Canada to the mother country are very real, and that it is the duty of all good citizens of the Empire to keep that chain intact by losing no opportunities of mutual comprehension and sympathy.

On the same afternoon the honorary degree of LL.D. of the University of Toronto was conferred upon 14 distinguished members of the Association[4] and visitors. The Dean of the Faculty of Medicine, Dr. Reeve, in presenting the recipients of the honour to Dr. Maurice Hutton, acting-President of the University, referred to the position and attainments of those present, and of Dr. Langley Browne, chairman of the Council of the British Medical Association, who received the degree *in absentiâ*. Speeches in reply were made by Sir William Broadbent on behalf of the British physicians honoured, by Mr. Franklin on behalf of the British surgeons, by Professor W. D. Halliburton on behalf of British physiologists, and by Dr. Lapicque on behalf of the French, German, and American recipients of the degree. It was further announced by Professor William Gardner of Montreal that at the next Convocation of McGill University, Montreal, the honorary degree of LL.D. would be conferred *in absentiâ* upon Sir Thomas Barlow, Sir William Broadbent, Professor Clifford Allbutt, and Sir Victor Horsley.

The annual pathological museum was held in the first floor rooms of the medical laboratories, in the same building as the pathological museum of the University of Toronto. The exhibits were of exceptional interest and included a series of specimens illustrating Dr. Klotz's paper on Experimental Arterio-Sclerosis, a series of specimens of congenital disease of the heart, and a series of photographs illustrating the facies of disease. One of the most interesting exhibits was that of Dr. W. H. Watters, of Boston University, Massachusetts, which comprised about 600 pathological specimens illustrating a gelatin method of mounting museum specimens. The preparations are first made by Kaiserling's method and afterwards placed in a solution of gelatin, glycerine, and potassium acetate, to which a little formalin is added. The specimen is put in place while the gelatin is liquid, and it is then allowed to solidify. This method preserves the colour better than the ordinary method of mounting in glycerine, while the specimen need not be kept away from the light. The gelatin remains clear and is prevented from melting, even in hot weather, by the formalin. This method has been in use for about five years and has given satisfactory results as regards permanency. Judged by the specimens shown it is an eminently satisfactory method. There were also a skiagraphic exhibit and a number of plaster casts of orthopædic conditions.

The annual exhibition was held in two large rooms and several smaller ones on the first floor of the main building of the University of Toronto, which is a handsome Norman Gothic building, beautifully situated in the university park behind the university buildings. It was therefore very conveniently situated for the members and visitors, being in the same building as the offices, registration rooms, and several of the sections. The rooms were decorated by a series of paintings and photographs illustrating scenes in Canadian life. Although there was a fairly large number of exhibits, with a few exceptions there were none of especial interest or novelty. The usual prominent British firms were represented, and there was an unusually large number of American exhibitors, as might have been expected, but of actual Canadian firms there were but few. Hospital furniture, operation tables, instruments, and special foods were much displayed, but the electrical exhibits and mechanical apparatus were among the most interesting exhibits. There were comparatively few new pharmaceutical preparations exhibited.

We should like to take the earliest opportunity of expressing our thanks to the many officers of the British Medical Association and residents in Toronto who have given us assistance and welcome.

OPENING OF THE LONDON MEDICAL SCHOOLS.

WINTER SESSION, 1906–07.

St. Bartholomew's Hospital.—The session will be opened on Oct. 1st by a dinner of old students in the great hall of the hospital.

Charing Cross Hospital.—The winter session will commence on Oct. 1st by the delivery of the sixth biennial Huxley lecture on Recent Advances in Science and their Bearing on Medicine and Surgery, in the anatomical theatre of the medical school at 4 P.M., by Professor Ivan Petrovitsch Pawlow of St. Petersburg. The dinner of the past and present students will take place on the evening of the same day.

St. George's Hospital.—The session will begin on Oct. 1st. The inaugural address will be delivered and the prizes presented by the Right Reverend the Bishop of Bristol on the same afternoon at 3 P.M. The annual dinner will be held in the evening at 6 30 for 7 at the Whitehall Rooms, Hôtel Métropole, Mr. Clinton T. Dent, senior surgeon to the hospital, being in the chair.

Guy's Hospital.—The session will commence on Oct. 1st and the opening meeting of the Pupils' Physical Society will be held on Oct. 13th at 8 P.M., when an address will be delivered by Professor T. Clifford Allbutt.

King's College Hospital.—The session will open on Oct. 2nd with an introductory lecture by Mr. Pridgin Teale, F.R.S. The old students' dinner will be held at the Hotel Cecil on the evening of the same day when Dr. Nestor Tirard will preside.

London Hospital.—The Winter Session will commence on Oct. 1st. The annual dinner will take place the same evening at 7.30 at Princes Restaurant; Mr. John Holroyde of Rochester will be in the chair. In the afternoon of the same day members of the staff will be at home in the library of the College to receive old students and to show them the recent additions and improvements to the hospital and College.

St. Mary's Hospital.—The Winter Session will open on Monday, Oct. 1st, with an Introductory Address by Dr. N. H. Alcock, lecturer on physiology and vice-dean of the Medical School. The annual dinner of past and present students will be held at the Whitehall Rooms, Hôtel Métropole, on Tuesday, Oct. 2nd, at 7 P.M., with Dr. M. Handfield-Jones in the chair.

Middlesex Hospital.—The session will open on Oct. 1st, when Dr. H. Campbell Thomson will deliver the inaugural address. The students' dinner will be held at the Trocadéro Restaurant on the same evening.

St. Thomas's Hospital.—The session will commence on Oct. 1st. On the same evening the old students' dinner will be held at the Hotel Cecil.

University College Hospital.—The session will be opened on Oct. 2nd at 4 P.M. by Professor R. J. Godlee, who will deliver the inaugural address on the Past, Present, and Future of the Medical School. The annual dinner will be held on the same day at 7 P.M. at the Hotel Cecil. Professor G. D. Thane will preside.

Westminster Hospital.—The session will begin on Oct. 1st. The annual dinner will take place on the opening day at the Trocadéro, Dr. F. de Havilland Hall, being in the chair. The secretary of the dinner is Mr. E. Rock Carling, 38, New Cavendish-street, W.

---

[4] Sept. 1st, 1906, p. 625.

London (Royal Free Hospital) School of Medicine for Women.—The session will begin on Oct. 1st when Professor J. W. Byers will deliver an inaugural address on Medical Women and Public Health Problems at 4 P.M.

London School of Tropical Medicine.—The session will commence on Oct. 1st. The inaugural address will be delivered on Oct. 8th by Colonel Kenneth Macleod, I.M.S., when the Duke of Marlborough will occupy the chair.

MEDICINE AND THE LAW.

Medical Men and a Begging Letter Impostor.

Bruno Kohnfeldt is a German "described as a doctor," who apparently possesses enough education to be useful to him in a career of fraud without enabling him to make an honest living, for, according to his own evidence and that of the police, he has been since his release on ticket-of-leave in a very weak state due to starvation. He has, genuinely no doubt, tried to make money by journalism but has also written a large number of begging letters, in at least one of which he represented himself as a medical man, although he gave an address at which no surgery exists and no medical man resides. This letter was addressed to Bishop Kelly, late Bishop of Moray, and was couched in specious terms, recommending as an object of charity an imaginary patient stated to be an old university man in distressed circumstances. Medical men, who are especially liable to be the victims of impostors of this class are reminded that their own names and addresses, with the particulars of their educational careers, are open to the inspection of all who choose to make use of the numerous free libraries now in existence, and also that the claims made by honest but unfortunate people are rarely of so urgent a nature as to leave no time for inquiry and verification. Kohnfeldt has been sent to prison for nine months, in addition to which, we believe, he will have to serve the balance of his term of penal servitude, and he has expressed a wish, which we hope may be granted, to be deported eventually to his own country.

Child Insurance and Child Murder.

A very bad case of child insurance followed by cruel neglect of the assured, was brought to light recently at the Willesden police court. The persons charged were a man and woman living together in a house which was described by an inspector of the National Society for the Prevention of Cruelty to Children as clean, while the same witness deposed that the children were well cared for. The subject of the prosecution was the child of the male prisoner. He was a little boy, five years of age. He was filthy, ill clad, and emaciated, he was allowed to sleep where he could, and was so weak that he could hardly stand. An insurance agent gave evidence that he had been insured since May, 1905, at a halfpenny a week at first but later at a penny, and that on his death a sum of £5 would have been received by those whose duty it was to feed and maintain him. Naturally in such a case the most important evidence was that of a medical witness. Mr. Walter E Turner, medical officer at the Willesden Union Infirmary, described the condition of the little boy upon admission there, when he weighed 16 pounds, and explained to the bench that the normal weight of a child of his age would have been about 40 pounds. He had no organic disease and in the infirmary took food well, gaining 5 pounds in the first week and 11½ pounds during the interval between his admission and the date of the hearing of the charge. Mr. Turner was of opinion that the starvation had gone on for months, and that in a fortnight or three weeks it must have had its natural result in the child's death. The magistrate, Mr. George Wright, sentenced both prisoners to six months' hard labour. Those who feel satisfaction at this result and who, perhaps, regret that it was not possible to inflict a more severe punishment, will, no doubt, wish that child insurance, which may form a useful and praiseworthy provision against emergencies on the part of poor parents, should be so controlled as not to constitute a source of temptation to the cruel and covetous. It should not be impossible to render compulsory a system of inspection, to be established at the expense of the insurance companies, and to be applied in all cases where the lives of children are insured. The companies could hardly complain as the result of such inspection would be to diminish the number of unjustifiable claims made against them. The argument that it would diminish the number of insured children on their books would hardly be considered in their favour.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8784 births and 5592 deaths were registered during the week ending August 25th. The annual rate of mortality in these towns, which had steadily increased in the six preceding weeks from 11·7 to 17·0 per 1000, further rose to 18·4 during the week under notice. During the first eight weeks of the current quarter the death-rate in these towns averaged 14·1 per 1000, the rate during the same period in London being 14·0. The lowest death-rates in the 76 towns for the week were 8·1 in Smethwick, 8·4 in Southampton, 8·6 in King's Norton, and 9·2 in Reading; the rates in the other towns ranged upwards to 24·2 in Liverpool, 24·9 in Birkenhead, 25·9 in Coventry, 28·3 in Stockport, 29·2 in Wigan, and 29·7 in Yarmouth. The 5592 deaths in the 76 towns showed a further increase of 435 upon the numbers returned in recent weeks, and included 1876 which were referred to the principal epidemic diseases, against numbers increasing from 361 to 1623 in the six preceding weeks; of these no fewer than 1651 resulted from diarrhœa, 73 from measles, 53 from whooping-cough, 49 from diphtheria, 25 from scarlet fever, 25 from "fever" (principally enteric), and not one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 6·2 per 1000 in the 76 towns and to 5·6 in London. No death from any of these epidemic diseases was registered during the week under notice in Handsworth, and the annual death-rate therefrom, was under 1 per 1000 in Bournemouth, Reading, and King's Norton; whereas they caused rates equal to 11·4 in Aston Manor, 11·5 in Birmingham, 13·3 in Birkenhead, 13·8 in West Ham, and 15·7 in Stockport. The deaths (mainly of infants under one year) referred to diarrhœa, which had steadily increased in the 11 preceding weeks from 50 to 1385, further rose in the week to 1651; the highest annual rates from this disease being 10·8 in Birmingham, 10·9 in Nottingham, 11·4 in West Ham, 12·4 in Birkenhead, and 13·6 in Stockport. The largest proportional fatality from measles occurred in South Shields, Stockport, Norwich, and Rotherham; and from whooping-cough in Walsall and Rotherham. Of the 49 deaths from diphtheria nine occurred in London, four in West Ham, and two each in Derby, Liverpool, Manchester, Halifax, Bradford, Hull, Middlesbrough, and Newcastle-upon-Tyne. Scarlet fever caused nine deaths in London, two in Liverpool, two in Bradford, and two in Middlesbrough. Three deaths were referred to "fever" in West Ham and two in Hull. No case of small-pox was under treatment in the Metropolitan Asylums hospitals during the week, no case having been admitted since the end of June. The number of scarlet fever cases under treatment in the Metropolitan Asylums hospitals and in the London Fever Hospital, which had been 3051 and 3046 at the end of the two preceding weeks, rose in the week under notice to 3078; 350 new cases were admitted to these hospitals during the week, against 415, 308, and 317 in the three preceding weeks. The deaths referred to pneumonia and other diseases of the respiratory organs in London, which had steadily increased in the four preceding weeks from 101 to 119, declined again to 103, and were 17 below the corrected average in the corresponding week of the four preceding years, 1902–05. The causes of 47, or 0·8 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner. All but one of the causes of death were duly certified in London, and all were so certified in Bristol, Leeds, Leicester, Hull, Salford, and in 48 other of the large towns; the proportion of uncertified causes of death showed, however, a considerable excess in Liverpool, Sheffield, and Preston.

In 76 of the largest English towns 8663 births and 5556 deaths were registered during the week ending Sept. 1st. The annual rate of mortality in these towns, which had steadily increased in the seven preceding weeks from 11·7 to 18·4 per 1000, slightly declined to 18·3 during the week

On the same day a luncheon was given by the Empire Club in the clubhouse of the Royal Canadian Yacht Club on Toronto Island. The weather, in spite of a recurrence of thunderstorms, was bright and clear. Some very interesting speeches were made, the note of one and all being that the links binding Canada to the mother country are very real, and that it is the duty of all good citizens of the Empire to keep that chain intact by losing no opportunities of mutual comprehension and sympathy.

On the same afternoon the honorary degree of LL.D. of the University of Toronto was conferred upon 14 distinguished members of the Association[4] and visitors. The Dean of the Faculty of Medicine, Dr. Reeve, in presenting the recipients of the honour to Dr. Maurice Hutton, acting-President of the University, referred to the position and attainments of those present, and of Dr. Langley Browne, chairman of the Council of the British Medical Association, who received the degree *in absentiâ*. Speeches in reply were made by Sir William Broadbent on behalf of the British physicians honoured, by Mr. Franklin on behalf of the British surgeons, by Professor W. D. Halliburton on behalf of British physiologists, and by Dr. Lapicque on behalf of the French, German, and American recipients of the degree. It was further announced by Professor William Gardner of Montreal that at the next Convocation of McGill University, Montreal, the honorary degree of LL.D. would be conferred *in absentiâ* upon Sir Thomas Barlow, Sir William Broadbent, Professor Clifford Allbutt, and Sir Victor Horsley.

The annual pathological museum was held in the first floor rooms of the medical laboratories, in the same building as the pathological museum of the University of Toronto. The exhibits were of exceptional interest and included a series of specimens illustrating Dr. Klotz's paper on Experimental Arterio-Sclerosis, a series of specimens of congenital disease of the heart, and a series of photographs illustrating the facies of disease. One of the most interesting exhibits was that of Dr. W. H. Watters, of Boston University, Massachusetts, which comprised about 600 pathological specimens illustrating a gelatin method of mounting museum specimens. The preparations are first made by Kaiserling's method and afterwards placed in a solution of gelatin, glycerine, and potassium acetate, to which a little formalin is added. The specimen is put in place while the gelatin is liquid, and it is then allowed to solidify. This method preserves the colour better than the ordinary method of mounting in glycerine, while the specimen need not be kept away from the light. The gelatin remains clear and is prevented from melting, even in hot weather, by the formalin. This method has been in use for about five years and has given satisfactory results as regards permanency. Judged by the specimens shown it is an eminently satisfactory method. There were also a skiagraphic exhibit and a number of plaster casts of orthopædic conditions.

The annual exhibition was held in two large rooms and several smaller ones on the first floor of the main building of the University of Toronto, which is a handsome Norman Gothic building, beautifully situated in the university park behind the university buildings. It was therefore very conveniently situated for the members and visitors, being in the same building as the offices, registration rooms, and several of the sections. The rooms were decorated by a series of paintings and photographs illustrating scenes in Canadian life. Although there was a fairly large number of exhibits, with a few exceptions there were none of especial interest or novelty. The usual prominent British firms were represented, and there was an unusually large number of American exhibitors, as might have been expected, but of actual Canadian firms there were but few. Hospital furniture, operation tables, instruments, and special foods were much displayed, but the electrical exhibits and mechanical apparatus were among the most interesting exhibits. There were comparatively few new pharmaceutical preparations exhibited.

We should like to take the earliest opportunity of expressing our thanks to the many officers of the British Medical Association and residents in Toronto who have given us assistance and welcome.

OPENING OF THE LONDON MEDICAL SCHOOLS.

Winter Session, 1906–07.

St. Bartholomew's Hospital.—The session will be opened on Oct. 1st by a dinner of old students in the great hall of the hospital.

Charing Cross Hospital.—The winter session will commence on Oct. 1st by the delivery of the sixth biennial Huxley lecture on Recent Advances in Science and their Bearing on Medicine and Surgery, in the anatomical theatre of the medical school at 4 P.M., by Professor Ivan Petrovitsch Pawlow of St. Petersburg. The dinner of the past and present students will take place on the evening of the same day.

St. George's Hospital.—The session will begin on Oct. The inaugural address will be delivered and the p presented by the Right Reverend the Bishop of Bristol on same afternoon at 3 P.M. The annual dinner will be hel the evening at 6 30 for 7 at the Whitehall Rooms, H Métropole, Mr. Clinton T. Dent, senior surgeon to hospital, being in the chair.

Guy's Hospital.—The session will commence on Oct. and the opening meeting of the Pupils' Physical Society be held on Oct. 13th at 8 P.M., when an address will delivered by Professor T. Clifford Allbutt.

King's College Hospital.—The session will open Oct. 2nd with an introductory lecture by Mr. Pridgin Te F.R.S. The old students' dinner will be held at the H Cecil on the evening of the same day when Dr. Nestor Ti will preside.

London Hospital.—The Winter Session will commence Oct. 1st. The annual dinner will take place the same even at 7.30 at Princes Restaurant; Mr. John Holroyde Rochester will be in the chair. In the afternoon of the sa day members of the staff will be at home in the library the College to receive old students and to show them t recent additions and improvements to the hospital a College.

St. Mary's Hospital.—The Winter Session will open Monday, Oct. 1st, with an *Introductory Address* by D N. H. Alcock, lecturer on physiology and vice-dean of th Medical School. The annual dinner of past and prese students will be held at the Whitehall Rooms, Hôt Métropole, on Tuesday, Oct. 2nd, at 7 P.M., with Dr. Handfield Jones in the chair.

Middlesex Hospital.—The session will open on Oct. 1s when Dr. H. Campbell Thomson will deliver the inaugura address. The students' dinner will be held at the Trocadér Restaurant on the same evening.

St. Thomas's Hospital.—The session will commence o Oct. 1st. On the same evening the old students' dinner wil be held at the Hotel Cecil.

University College Hospital.—The session will be opened on Oct. 2nd at 4 P.M. by Professor R. J. Godlee, who will deliver the inaugural address on the Past, Present, and Future of the Medical School. The annual dinner will be held on the same day at 7 P.M. at the Hotel Cecil. *Professor* G. D. Thane will preside.

Westminster Hospital.—The session will begin on Oct. 1st. The annual dinner will take place on the opening day at the Trocadéro, Dr. F. de Havilland Hall, being in the included 28 which were referred to the principal epidemic diseases, against 32 and 27 in the two previous weeks; these 28 deaths were equal to an annual rate of 3·9 per 1000, the death-rate in the week from the same diseases being 5·6 in London and 1·4 in Edinburgh. Of these 28 deaths, 27 were referred to diarrhœa (against 29 and 27 in the two previous weeks), one to "fever," and not one to small-pox, measles, scarlet fever, diphtheria, or whooping-cough. The deaths of infants showed a decline from the high number in the previous week, and those of elderly persons were below the average. Eight inquest cases and seven deaths from violence were registered; and 50, or 37·7 per cent., of the deaths occurred in public institutions. The causes of all but one of the deaths registered during the week were duly certified.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments are notified:—Fleet Surgeons: F. A. Brice to the *Excellent*, for the *Revenge*, on recommissioning; J. McElwee to the *Britannic*, on commissioning; F. Fedarb to the *Dreadnought*, on commissioning; and E. C. Lomas to the *President*, for three months' study at Edinburgh University. Staff Surgeons: R. Waterfield to the *Excellent*, for the *Revenge*, on recommissioning; W. H. Thomson to the *President*, for three months' course at West London Hospital; H. H. Pearse to the *Minerva* and R. T. Gilmour to the *Talbot*, on recommissioning; J. C. Watt to the *Pelorus* and E. F. Mortimer to the *Sirius*, on recommissioning. Surgeons: J. Bourdas to the *Impregnable*, for dental duties; H. L. Norris to the *Sappho;* E. S. Tuck to the *Scylla* on recommissioning; W. F. Keir to the *Vernon*, for the *Furious;* H. Woods to the *Minerva*, on recommissioning; and P. D. MacJ. Campbell, to the *Sealark*.

Royal Army Medical Corps.

The undermentioned Lieutenant Colonels retire on retired pay (dated August 25th, 1906):—William H. Pinches, Michael J. Whitty, and Willington S. Dowman. Lieutenant George De la Cour from the Seconded List to be Lieutenant (dated August 1st, 1906). The undermentioned Lieutenants to be Captains (dated July 31st, 1906): John G. Bell, Maurice G. Winder, Frederick W. W. Dawson, Joseph E. H. Gatt, Robert M. Ranking, Thomas S. Coates, Albert E. B. Wood, James C. G. Carmichael, Roland H. Bridges, James A. W. Webster, Francis C. Lambert, James B. Meldon, Reginald C. Wilmot, Charles W. Holden, Harry B. Kelly, Edward M. Pennefather, George H. J. Brown, Benjamin H. V. Dunbar, David Ahern, Donald G. Carmichael, John M. M. Crawford, Charles Bramhall, Thomas E. Harty, Henry H. Swanzy, John H. Duguid, Henry T. Stack, Burnet G. Patch, and Geoffrey W. G. Hughes. The undermentioned Lieutenants are seconded under the provisions of Article 349 Royal Warrant, March 19th, 1906 (dated July 30th, 1906):—Benjamin Johnson, and William E. C. Lunn. The undermentioned gentlemen to be Lieutenants on probation (dated July 30th, 1906):—Gerald Hoey Stevenson, John Heatly Spencer, William Henry Forsyth, Alfred Herbert Heslop, Archibald Craig Amy, Wright Mitchell, James Archibald Bruce Sim, Edward John Elliot, Ernest Browning Lathbury, Edward Gibbon, Cecil Scaife, Robert Walter Dixon Leslie, Ernest Duncan Caddell, Michael Joseph Lochrin, Daniel Maurice Corbett, Benjamin Johnson, William Ernest Craven Lunn, John Rowland Foster, Arthur Hildebrand Jacob, Arthur Morris Benett, Francis Lyndon Bradish, George Philip Alexander Bracken, Owen Cunninghame Preston Cooke, William Wallace Boyce, Carlisle Kelly, Clarence Hamul Denver, Whiteford John Edward Bell, Duncan Coutts, William Francis Mary Loughnan, Dennis Thomas MacCarthy, Hector Lionel Howell, Charles William Bowle, John Joseph O'Keeffe, James Alexander Bennett, Thomas Walker Browne, William Irwin Thompson, Reginald Charles Galgey, Edward James Kavanagh, and Ernest Cyril Phelan.—Major G. B. Stanistreet has been appointed Staff Officer to the Principal Medical Officer of the Southern Command. Colonel E. North has been appointed Administrative Medical Officer in Dublin. Captain E. W. W. Cochrane has been selected to succeed Lieutenant-Colonel H. C. B. Elkington as sanitary officer to the Aldershot Army Corps. Captain S. A. Archer, on duty in Dublin, has been selected for Specialist in Ophthalmology in Ireland. Major C. R. Elliott, Fermoy, has been approved for appointment as a sanitary officer in the Irish command, with specialist pay, vice Lieutenant-Colonel R. L. R. Macleod, Dublin, who leaves for India in October. Lieutenant-Colonel R. W. Ford, D.S.O., has joined the London district for duty. Major J. Thomson has assumed medical charge of Military Families Hospital at Woolwich, vice Lieutenant-Colonel R. J. C. Cottell. Major G. St. C. Thom, having been ordered for service in India, has been succeeded as Adjutant of the Depôt and Training School, Royal Army Medical Corps, at Aldershot, by Captain E. T. F. Birrell from the Royal Army Medical College. Colonel P. M. Ellis has been appointed Administrative Medical Officer in India.

Indian Medical Service.

Lieutenant-Colonel J. Carmichael, R.A.M.C., has been appointed to the command of the Station Hospital, Jullundur.

Army Medical Reserve of Officers.

Surgeon-Lieutenant James N. Macmullan to be Surgeon-Captain (dated August 14th, 1906).

Volunteer Corps.

Rifle: 1st Volunteer Battalion, the Queen's (Royal West Surrey Regiment): Walter Gray Paget to be Surgeon-Lieutenant (dated August 25th, 1906). 4th Volunteer Battalion, the South Wales Borderers: Surgeon-Lieutenant W. P. Miles resigns his commission (dated August 25th, 1906). 1st Lanarkshire Volunteer Rifle Corps: Surgeon-Lieutenant R. H. Henderson to be Surgeon-Captain (dated August 25th, 1906). 3rd (the Blythswood) Volunteer Battalion, the Highland Light Infantry: Surgeon-Lieutenant P. M. Dewar to be Surgeon-Captain (dated August 25th, 1906). 24th Middlesex Volunteer Rifle Corps: Wyndham Anstruther Milligan to be Surgeon-Lieutenant (dated August 4th, 1906). 4th Volunteer Battalion, the Royal Fusiliers (City of London Regiment): John Kilpatrick Brownlees to be Surgeon-Lieutenant (dated August 29th, 1906).

Royal Hospital, Chelsea.

Lieutenant-Colonel Reginald J. C. Cottell has been appointed Deputy-Surgeon of the Royal Hospital, Chelsea, vice Lieutenant-Colonel R. W. Ford, D.S.O., whose tenure of that appointment has expired (dated August 17th, 1906).

Deaths in the Services.

Surgeon Herbert Bartlett Simpson, R.N., of the *Sealark*, on August 28th, at Diyatalawa, Ceylon (naval camp), in his twenty-ninth year. He was appointed surgeon in November, 1902.

Outbreak of Enteric Fever at Fleetwood Camp.

The serious outbreak of enteric fever in the officers' mess of the Militia battalion of the Loyal North Lancashire Regiment at Fleetwood calls for a searching investigation, which, indeed, it is bound to have. The outbreak in question, which is reported to have caused the death of three officers, was of an explosive nature and apparently circumscribed within very narrow limits. It was so strongly indicative of some common cause, and that of a concentrated kind, as to suggest at once water poisoning, and this very naturally appears to have been the direction of the inquiries that have so far been instituted. The training camp is the property of the Crown and at a little distance from the town. The outbreak of enteric fever was limited to the officers' mess, and the food is believed to have been altogether beyond suspicion. The water supplied to the camp is the same as that supplied to the town of Fleetwood and all neighbouring places, and Fleetwood's bill of health is quite clear. But all the dates and facts connected with the medical history of the occurrence, and the results of the bacteriological and other investigations, have still to be obtained.

Rifle Teaching at School.

We are glad to notice that the school rifle movement is being widely followed. The training of the hand and eye is useful and interesting to boys, and its beneficial effect will probably be seen in such other pursuits and occupations as they take up in the course of their lives. There are reasons also of a disciplinary and hygienic kind why a course of rifle shooting and elementary military drill should prove useful.

The Volunteer Officers' Decoration has been conferred on the under-mentioned medical officers:—Northern Command under notice. During the first nine weeks of the current quarter the death-rate in these towns averaged 14·5 per 1000, the rate during the same period in London being 14·4. The lowest death-rates in the 76 *towns during the* week were 7·2 in Northampton, 9·2 in Bournemouth, 10·1 in Hastings, *and 10·2 in Hornsey; the rates in the* other towns ranged upwards to 25·8 in Hull, 25·9 in Coventry, 28·7 in Yarmouth, and 30 4 in Stockport. The 5556 deaths in the 76 towns showed a decline of 36 from the high number in the previous week, and included 1977 which were referred to the principal epidemic *diseases*, against numbers increasing from 361 to 1875 in the seven preceding weeks; of these no fewer than 1765 resulted from diarrhœa, 64 from measles, 55 from whooping-cough, 37 from diphtheria, 34 from scarlet fever, 26 from "fever" (principally enteric), and not one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 6·5 per 1000 in the 76 towns and to 5·6 in London. The annual rate from these epidemic diseases during the week ranged from 0 5 per 1000 in Halifax, 0·7 *in Devonport, and 0 8 in* Bournemouth, to 12·0 in Stockport and in Aston Manor, 12·3 in Coventry, and 12·7 in Salford. The deaths referred to diarrhœa (mainly of infants under one year), which had *steadily increased in the 12 preceding weeks from* 50 to 1649, further rose during the week to 1765; the highest annual *rates from this disease during the week were 9·6* in Nottingham, 9·8 in *Grimsby, 9 9* in West Ham, 11·4 in Aston Manor and in Salford, *and 12·3 in Coventry. The* largest proportional mortality from measles occurred in Wigan, Rotherham, and Stockport; and from whooping-cough in Huddersfield, Birkenhead, and Merthyr Tydfil. Scarlet fever caused seven deaths *in London*, six in Sheffield, three in Liverpool, and two in Swansea; and diphtheria 11 in London, and two each in St. Helens, Wigan, and Rochdale. Three deaths were referred to "fever" in West Ham. No case of small-pox was under treatment in the Metropolitan *Asylums hospitals* during the week and no case has been admitted thereto since the end of June. The number of scarlet fever cases under treatment in the Metropolitan Asylums hospitals and in the London Fever hospital, which had been 3046 and 3078 at the end of the two preceding weeks, declined in the week under notice to 3042; 317 new cases were admitted to these hospitals during the week, against 317 and 350 in the two preceding weeks. The deaths referred to pneumonia and other diseases of the respiratory organs *in London which had been* 119 *and* 103 in the two previous weeks, rose again during the week to 109, but were *19 below the corrected average in the corresponding week of* the four preceding years 1902–05. The causes of 57, or 1·0 *per cent., of the deaths registered in the 76 towns during* the week were not certified either by a registered medical *practitioner or by a coroner. All the causes of death were* duly certified in Bristol, Salford, Leicester, Nottingham, and *in 45 of the large towns; the proportion of uncertified* causes showed, however, a considerable *excess* in Liverpool, St. Helens, Rochdale, Preston, Sunderland, and *Gateshead.*

HEALTH OF SCOTCH TOWNS.

The annual rate of *mortality* in eight of the *principal* Scotch towns, which had been equal to 11·8, 14·0, and 14·8 per 1000 in the three preceding weeks, *declined again to 13 8* in the week ending August 25th and was 4 6 below the mean rate in the same week *in the 76 English towns. The* rates in the eight Scotch towns ranged from 10·6 and 11·4 in Perth and Leith to 16·2 and 16 5 *in Aberdeen.* The 472 deaths in the eight *towns* showed a decline of 20 from the number returned in the previous week, and included 79 which resulted from the *principal* epidemic diseases, against 64 and 61 in the two previous weeks; *these 79 deaths were* equal to an annual rate of 2·3 per 1000, which was no less than 3·9 below the rate from the same *diseases in the 76* English towns. Of these 79 deaths, 54 were referred to diarrhœa, 11 to whooping-cough, six to "fever," four to diphtheria, three to measles, one to scarlet fever, and not one to small-pox. The deaths *attributed to diarrhœa* in the Scotch towns, which had steadily increased in the five preceding weeks from 11 to 37, *further rose* last week to 54, of which 30 occurred in Glasgow, six in Edinburgh, and five in Greenock. Nine fatal cases *of whooping-cough*, five *of "fever"* (including four certified as cerebro-spinal meningitis), three of diphtheria, and two *of measles* were also returned in Glasgow. The mortality from epidemic disease, other than diarrhœa, was *exceptionally* low in the other Scotch towns. The deaths in the eight towns referred *to diseases* of the respiratory organs, including pneumonia, which had been 68 in each of the two preceding weeks, declined in the week under notice to 52, but exceeded by eight the low number returned in the corresponding week of last year. The causes of 21, or 4·0 per cent., of the deaths registered during the week were not certified; the proportion of uncertified causes of death in the English towns did not exceed 0·8 per cent.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 14·8 and 13·8 *per 1000 in the two preceding* weeks, *rose again to 14·2* in the week ending Sept. 1st, and was 4·1 below the mean rate in the same week in the 76 English towns. The rates in the eight Scotch *towns* ranged from 11·4 and 11·5 in Paisley and Edinburgh to 19·6 in Perth and 22·9 in Greenock. *The 487 deaths in the eight towns* showed an increase of 15 upon the number returned in *the previous week, and included 80 which were referred* to the principal epidemic diseases, against 61 and 79 in the *two previous weeks; these 80 deaths were equal to an* annual rate of 2·3 per 1000, which was no less than 4·2 below the rate from the same diseases *in the 76 English towns. Of these 80 deaths* 48 resulted from diarrhœa, *11* from whooping-cough, 10 from "fever," five *from diphtheria, three from* measles, two from scarlet fever, and one from chicken-pox. The deaths attributed to diarrhœa in the Scotch towns, which had *steadily* increased in the six preceding weeks from 11 to 54, declined last week to 48, of which *28 occurred* in Glasgow, six in *Dundee*, four in Edinburgh, and *three both* in Paisley and Greenock. Eight of the 11 fatal cases of whooping-cough were returned in Glasgow and two in Aberdeen; nine of the ten deaths referred to "fever" (including four certified as cerebro-spinal *meningitis*) were *also returned in Glasgow.* Three fatal cases of diphtheria were recorded in Edinburgh and two in Glasgow. The deaths in the eight towns referred to diseases *of the respiratory* organs, including pneumonia, which had been 68 and 52 in the two preceding weeks, rose again to 61 in the week under notice, and exceeded by eight the low number returned in the corresponding week *of last year.* The causes of 17, or 3·5 per cent., of the *deaths registered during* the week were not certified; the mean *proportion* of uncertified deaths in the 76 English towns did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal *to* 16 8, 17·3, and 19·7 in the three *preceding* weeks, further rose to 21·5 *during* the week ending August 25th. *During the first eight* weeks of the current quarter the death-rate in the city averaged 19·0 per 1000, the mean death-*rates during the same period* being 14·0 in London and 12 8 in Edinburgh. The 156 deaths of Dublin residents *during* the week under notice showed a further increase of 13 upon the numbers *returned in the three* preceding *weeks, and included* 27 which were referred to the principal epidemic diseases, against *19 and 32 in the two previous weeks; these 27 deaths were* equal to an annual rate of 3·7 per 1000, the death-rate in the week from the same diseases *being 5 6 in London* and 1·2 in Edinburgh. All these 27 deaths were referred to diarrhœa (against 10 and 29 in the *two previous weeks), no fatal* case of small-pox, scarlet fever, measles, diphtheria, whooping-cough, or "fever" *having been registered in the city* during the week. The deaths of infants showed a marked increase during the week, while those of *elderly* persons were below the average. Six inquest cases and eight deaths from violence were registered; and 48, or 30·8 per cent., of the deaths occurred in public institutions. The causes of all but two of the deaths registered during the week were duly certified.

The annual death-rate in Dublin, which had steadily increased from 16 8 to 21·5 *per 1000* in the four preceding weeks, further rose to 21·9 during the week ending Sept. 1st. During the first nine weeks *of the current quarter the death*-rate in the city averaged 19·3 per 1000, the mean death-rates during the same period *being 14 4 in London and 12·6 in Edinburgh.* The 159 deaths of Dublin residents during the week under notice showed a *further increase of three* upon the numbers returned in the four preceding weeks, and believe that an alteration in the regulations will be for the good of the institution which they administer and of the public which it serves) it is right that the change should be made. We cannot express any conclusion as to the legality of the action of the governors. As to its advisability. our general view is that any modification of hospital rules which *tends to break down artificial barriers, purporting to divide* the medical profession into classes and sections, is for the good of the profession and of the public. Very large questions are opened by this aspect of the matter.—ED. L.

THE TREATMENT OF IRITIS, INTERSTITIAL KERATITIS, &c., BY ACETOZONE.

To the Editors of THE LANCET.

SIRS,—During the last 16 months I have treated all my cases of intra ocular inflammation on the assumption that they were the result of bacterial action and with gratifying results. The *post hoc ergo propter hoc* fallacy of basing the constitutional treatment on such history as is obtainable from the patient has been so far the rule of practice and the possibility that there may be no connexion between the constitutional disease and the intra-ocular inflammation habitually lost sight of. Are we to ignore the possibility of *organisms* that have no connexion with venereal disease causing iritis in persons who are the victims of syphilis? Iritis would not be diagnosed as gonorrhœal iritis in a syphilitic subject were it not for the urethral discharge. In this form of iritis it is practically certain the ocular condition is due to circulating toxins, and if we may assume as much in syphilis, rheumatism, &c., very important results follow, for bacteriology furnishes us with proof of the importance of early treatment, as, for instance, in diphtheria, in which disease the antitoxin is almost useless after the fourth day. A most unsatisfactory feature of constitutional treatment in syphilis and rheumatism is the slowness of its action. If in these diseases early treatment is imperative we must infer the toxins have done their worst and specific remedies will have little effect. Toxins being almost certainly albumoses, it follows that the blood should be hurried as frequently as possible through the liver to convert these bodies into urea and to the kidneys and skin in order that the urea may be excreted, and this metabolism will be facilitated by systematic exercise and copious potations of water.

I have made it a routine practice for several years to inquire into the condition of the bowels in all cases of eye inflammations and find, especially in children, that they are mostly very foul, the association being so frequent that it can scarcely be a fortuitous one. In the treatment of such cases I used to begin by the internal administration of resorcin or salol, but the former sometimes produced quasi-carboluria and the latter was apt to make the patient ill. Having found that acetozone, as in typhoid fever, could be used with advantage as an intestinal and general antiseptic in eye diseases I gave it first in three-grain doses dissolved in four ounces of water. Subsequently I increased the amount of water largely and my present method is as follows. The patient drinks a tumbler of water and takes a three grain capsule of acetozone immediately, after which he walks briskly for ten minutes and then takes a second glass of water and again walks for ten or 15 minutes. Four doses are taken daily—before breakfast, in the middle of the morning, in the middle of the afternoon, and in the evening. The results have been satisfactory; so much so that one will never revert to the old methods, and especially as it is probable that still better results will be obtainable by the supplementary use of recognised drugs, such as the inunction of mercury, &c.

Altogether I have used the acetozone-hydrotherapeutic treatment in 45 cases of iritis, interstitial keratitis, &c., and also in one case of syphilitic optic neuritis and two cases of sympathetic ophthalmia. If the cases of iritis are seen early, say, before the fourth day, the patient not infrequently experiences relief from pain in a very few hours and we frequently find all redness gone by the sixth or seventh day. We should, of course, as a routine procedure dilate the pupil as much as possible at the first visit.

The following cases treated by acetozone are of interest. (a) A case of sympathetic iritis with keratitis punctata that had been under treatment off and on for 12 months in the ophthalmic department of a large metropolitan hospital. At the patient's first visit to the Croydon General Hospital on Dec. 16th vision was $\frac{6}{18}$; on Dec. 20th it was $\frac{6}{6}$. Three weeks later vision was normal and the eye appeared to have made a perfect recovery. The patient was seen about ten days ago and the eye remains free from all traces of deposit. (*b*) A second case of sympathetic iritis. This patient came to the Western Ophthalmic Hospital on Nov. 17th with vision reduced to counting fingers (Dr. F. Hewkley). On Nov. 24th vision was $\frac{6}{24}$; on Dec. 1st it was $\frac{6}{6}$, and slight keratitis punctata; on Jan. 19th there was *no trace of deposits* even under high magnification. This patient was seen three weeks ago and the eye seemed to be free from all trace of disease with the exception of a little uveal pigment on the lens.

In all nine cases of interstitial keratitis, several of extreme severity, were treated by acetozone. In one case not only was the cornea absolutely opaque and salmon-coloured but bulged in a most alarming way. In the course of six weeks the corneæ had cleared sufficiently for the patient to get about and the vision is now $\frac{6}{36}-\frac{6}{24}$. In a second case one eye was entirely lost before the child came under my care and the sight in the other was reduced to seeing hand movements at a few inches. This, however, was relieved in less than a week, although all previous remedies used in an ophthalmic hospital had proved unavailing and the mother's gratitude was profound. The child is *still under treatment* but as the disease had lasted for many months and the corneæ were leucomatous before the child came under my care it is improbable that there will be any considerable improvement in vision. A third case that has been under treatment for over six months gave excellent results as regards vision ($\frac{6}{6}$), although the patient was unable to carry out his instructions properly on account of his work. One case with salmon patches recovered in three months with vision $\frac{6}{6}$ and another in eight weeks with vision $\frac{6}{6}$. The remainder are still under treatment.
